

## Donor 7615

### Genetic Testing Summary

Fairfax Cryobank recommends reviewing this genetic testing summary with your healthcare provider to determine suitability.

Last Updated: 08/27/24

Donor Reported Ancestry: Nigerian

Jewish Ancestry: No

Genetic Test*	Result	Comments/Donor's Residual Risk**
Chromosome analysis (karyotype)	Normal male karyotype	No evidence of clinically significant chromosome abnormalities
Hemoglobin evaluation	Low MCV and MCH	<b>Alpha Thalassemia carrier</b> - confirmed by DNA testing-see below
Expanded Genetic Disease Carrier Screening Panel attached- 549 diseases by gene sequencing.	<b>Carrier: Alpha-Thalassemia (HBA1/HBA2) (a-/a-). Trait carrier</b>  Negative for other genes sequenced.	Partner testing is recommended before using this donor.

\*No single test can screen for all genetic disorders. A negative screening result significantly reduces, but cannot eliminate, the risk for these conditions in a pregnancy.

\*\*Donor residual risk is the chance the donor is still a carrier after testing negative.

**Patient Information**

Patient Name: Donor 7615

Date Of Birth:

Gender: Male

Ethnicity: African American/Black

Patient ID: N/A

Medical Record #: N/A

Collection Kit:

Accession ID: N/A

Case File ID:

Sample Collected: 04/04/2024

Sample Received: 04/05/2024

Sample Type: Blood

**CARRIER SCREENING REPORT**

**ABOUT THIS SCREEN:** Horizon™ is a carrier screen for specific autosomal recessive and X-linked diseases. This information can help patients learn their risk of having a child with specific genetic conditions.

**ORDER SELECTED:** The Horizon Custom panel was ordered for this patient. Males are not screened for X-linked diseases

**FINAL RESULTS SUMMARY:**

**CARRIER for Alpha-Thalassemia (a-/a-)**

Positive for the pathogenic alpha 3.7 deletions of the HBA2 genes. Carriers for Alpha-Thalassemia can sometimes have mild anemia. Comprehensive genetic counseling and additional medical workup as clinically indicated should be considered. Depending on the carrier status of the individual's partner, this couple may be at increased risk to have a child with Hemoglobin H Disease. Carrier screening for this individual's partner is suggested.

**Negative for 548 out of 549 diseases**

No other pathogenic variants were detected in the genes that were screened. The patient's remaining carrier risk after the negative screening results is listed for each disease/gene on the Horizon website at <https://www.natera.com/panel-option/h-all/>. Please see the following pages of this report for a comprehensive list of all conditions included on this individual's screen.

Carrier screening is not diagnostic and may not detect all possible pathogenic variants in a given gene.

**RECOMMENDATIONS**

Individuals who would like to review their Horizon report with a Natera Laboratory Genetic Counselor may schedule a telephone genetic information session by calling 650-249-9090 or visiting [naterasession.com](http://naterasession.com). Clinicians with questions may contact Natera at 650-249-9090 or email [support@natera.com](mailto:support@natera.com). Individuals with positive results may wish to discuss these results with family members to allow them the option to be screened. Comprehensive genetic counseling to discuss the implications of these test results and possible associated reproductive risk is recommended.

**ALPHA-THALASSEMIA****Understanding Your Horizon Carrier Screen Results****What is Alpha-Thalassemia?**

Alpha-Thalassemia refers to a group of inherited blood disorders that reduce the amount of hemoglobin, the protein in red blood cells that carries oxygen to cells throughout the body. A person with one of the Alpha-Thalassemia diseases has lifelong anemia. Mild anemia can lead to tiredness, irritability, dizziness, lightheadedness and a rapid heartbeat. Severe anemia can be life threatening and may require routine blood transfusions. In some cases, affected individuals have been treated with stem cell transplantation from cord blood or bone marrow. Couples at risk of having an affected child may consider cord blood banking, as siblings have a higher chance of being a match for stem cell transplantation than a non-related individual. More information can be found at: <https://parentsguidecordblood.org/en>. Clinical trials involving potential new treatments for these conditions may be available (see [www.clinicaltrials.gov](http://www.clinicaltrials.gov)).

**What causes Alpha-Thalassemia?**

Hemoglobin is made of both alpha globin and beta globin proteins. There are four HBA genes that are responsible for making alpha globin. Alpha-Thalassemia occurs when three or more of these four HBA genes (also called alpha globin genes) are missing or changed or when a person has changes, or mutations, called Constant Spring mutations, in two of the four genes. The exact type of Alpha-Thalassemia a person has depends on how many of the alpha globin genes are not working. Hemoglobin H Disease (a -/--) : three missing or changed alpha globin genes. A person who has three missing or changed alpha globin genes has Hemoglobin H Disease. Hemoglobin H Disease can be mild or severe. People with severe disease may have chronic anemia, liver disease, and bone changes. Some people with Hemoglobin H Disease require frequent blood transfusions and other treatments. Hemoglobin H-Constant Spring Disease: two missing alpha globin genes and one Constant Spring mutation. A person with these gene findings has Hemoglobin H-Constant Spring Disease. This condition is usually more severe than Hemoglobin H Disease. A person with this condition typically has chronic anemia, is more likely to need blood transfusions, has more frequent viral infections, and may have an enlarged spleen. Alpha-Thalassemia Major, also known as Hemoglobin Bart's Disease (--/--): four missing or changed alpha globin genes. This results in severe anemia. Affected babies develop symptoms before birth and without treatment typically do not survive the newborn period. Fetal blood transfusions during pregnancy may allow survival until after birth, at which time either lifelong transfusions or a stem cell transplantation will be necessary. Mothers pregnant with a fetus with Alpha-Thalassemia Major can develop health problems during pregnancy. Alpha-Thalassemia is inherited in an autosomal recessive manner. Children typically inherit four copies of each alpha globin gene, two copies from the mother and two copies from the father. This means that, in most cases, both parents must be carriers of one or more missing or changed alpha globin genes to have a child who is affected with Hemoglobin H Disease, Hemoglobin H-Constant Spring Disease, or Alpha-Thalassemia Major.

**What do my carrier results mean?**

Two missing alpha globin genes were identified with your Horizon test. People with two missing or changed alpha globin genes are carriers for Alpha-Thalassemia. Carriers can sometimes have mild anemia. If you have anemia or any other symptoms of thalassemia, you should discuss these issues with your health care provider. Thalassemia can occur in people of any ethnicity. It is more common in people with Chinese, Southeast Asian, Indian, Middle Eastern, African, and Mediterranean ancestry. If your results show that both of the missing or changed genes are on the same chromosome (in 'cis') and if your partner is also a carrier for Alpha-Thalassemia, you have at least a 1 in 4, or 25%, and depending on the type of mutations your partner has, an up to 1 in 2, or 50%, chance in each pregnancy of having a child with one of the Alpha-Thalassemia diseases. The majority of people of Asian ancestry who have two missing alpha globin genes have them on the same chromosome. The majority of people with African-American ancestry who have two missing alpha globin genes have them on opposite chromosomes and are not at increased risk to have a child with Alpha-Thalassemia Major. If your results show that the two missing or changed genes are on opposite chromosome (in 'trans'), and if your partner is a carrier for Alpha-Thalassemia with two genes missing on the same chromosome (in 'cis'), you would have a 50% chance to have a child with Hemoglobin H Disease but you are not at risk of having a child with Alpha-Thalassemia Major. If you and your partner are both carriers for Alpha-Thalassemia with two genes missing on opposite chromosomes ('trans'), all of your children would be carriers like you (two genes missing on opposite chromosomes) but you would not be at risk to have children with either Hemoglobin H Disease or Alpha-Thalassemia Major.

**What can I do next?**

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website ([www.nsgc.org](http://www.nsgc.org)). Your siblings and other relatives are at increased risk to also have these mutations. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for Alpha-Thalassemia ordered by a health care professional. If your partner is found not to be a carrier for Alpha-Thalassemia, your risk of having a child with Hemoglobin H Disease, Hemoglobin H-Constant Spring Disease, or Alpha-Thalassemia Major is greatly reduced. If your partner is found to be an Alpha-Thalassemia carrier, you may wish to discuss the results with your doctor or a genetic counselor to find out whether you have an increased risk to have children with any of the Alpha-Thalassemia diseases. Couples at risk of having a baby with one of the Alpha-Thalassemia diseases can opt to have prenatal diagnosis done through chorionic villus sampling (CVS) or amniocentesis during pregnancy or can choose to have the baby tested after birth for the specific Alpha-Thalassemia disease(s). If you are not yet pregnant, your partner can have carrier screening for Alpha-Thalassemia ordered by a health care professional. If your partner is found to be a carrier for Alpha-Thalassemia, you may wish to discuss the results with your doctor or a genetic counselor to find out whether you have an increased risk to have children with any of the Alpha-Thalassemia diseases. If you do, you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnostic testing of the fetus or testing the baby after birth for the indicated Alpha-Thalassemia diseases
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for the indicated Alpha-Thalassemia diseases
- Adoption or use of a sperm or egg donor who is not a carrier for Alpha-Thalassemia

**DISEASES SCREENED**

Below is a list of all diseases screened and the result. Certain conditions have unique patient-specific numerical values, therefore, results for those conditions are formatted differently.

**Autosomal Recessive**

**1**  
17-BETA HYDROXYSTEROID DEHYDROGENASE 3 DEFICIENCY (*HSD17B3*) **negative**

**3**  
3-BETA-HYDROXYSTEROID DEHYDROGENASE TYPE II DEFICIENCY (*HSD3B2*) **negative**  
3-HYDROXY-3-METHYLGLUTARYL-COENZYME A LYASE DEFICIENCY (*HMGCL*) **negative**  
3-HYDROXYACYL-COA DEHYDROGENASE DEFICIENCY (*HADH*) **negative**  
3-METHYLCROTONYL-CoA CARBOXYLASE 2 DEFICIENCY (*MCCC2*) **negative**  
3-PHOSPHOGLYCERATE DEHYDROGENASE DEFICIENCY (*PHGDH*) **negative**

**5**  
5-ALPHA-REDUCTASE DEFICIENCY (*SRD5A2*) **negative**

**6**  
6-PYRUVYL-TETRAHYDROPTERIN SYNTHASE ( *PTPS* ) DEFICIENCY (*PTS*) **negative**

**A**  
ABCA4-RELATED CONDITIONS (*ABCA4*) **negative**  
ABETALIPOPROTEINEMIA (*MTTP*) **negative**  
ACHONDROGENESIS, TYPE 1B (*SLC26A2*) **negative**  
ACHROMATOPSIA, CNGB3-RELATED (*CNGB3*) **negative**  
ACRODERMATITIS ENTEROPATHICA (*SLC39A4*) **negative**  
ACTION MYOCLONUS-RENAL FAILURE (AMRF) SYNDROME (*SCARB2*) **negative**  
ACUTE INFANTILE LIVER FAILURE, TRMU-RELATED (*TRMU*) **negative**  
ACYL-COA OXIDASE I DEFICIENCY (*ACOX1*) **negative**

**Testing Methodology, Limitations, and Comments:****Next-generation sequencing (NGS)**

Sequencing library prepared from genomic DNA isolated from a patient sample is enriched for targets of interest using standard hybridization capture protocols and PCR amplification (for targets specified below). NGS is then performed to achieve the standards of quality control metrics, including a minimum coverage of 99% of targeted regions at 20X sequencing depth. Sequencing data is aligned to human reference sequence, followed by deduplication, metric collection and variant calling (coding region +/- 20bp). Variants are then classified according to ACMGG/AMP standards of interpretation using publicly available databases including but not limited to ENSEMBL, HGMD Pro, ClinGen, ClinVar, 1000G, ESP and gnomAD. Variants predicted to be pathogenic or likely pathogenic for the specified diseases are reported. It should be noted that the data interpretation is based on our current understanding of the genes and variants at the time of reporting. Putative positive sequencing variants that do not meet internal quality standards or are within highly homologous regions are confirmed by Sanger sequencing or gene-specific long-range PCR as needed prior to reporting.

Copy Number Variant (CNV) analysis is limited to deletions involving two or more exons for all genes on the panel, in addition to specific known recurrent single-exon deletions. CNVs of small size may have reduced detection rate. This method does not detect gene inversions, single-exonic and sub-exonic deletions (unless otherwise specified), and duplications of all sizes (unless otherwise specified). Additionally, this method does not define the exact breakpoints of detected CNV events. Confirmation testing for copy number variation is performed by specific PCR, Multiplex Ligation-dependent Probe Amplification (MLPA), next generation sequencing, or other methodology.

This test may not detect certain variants due to local sequence characteristics, high/low genomic complexity, homologous sequence, or allele dropout (PCR-based assays). Variants within noncoding regions (promoter, 5'UTR, 3'UTR, deep intronic regions, unless otherwise specified), small deletions or insertions larger than 25bp, low-level mosaic variants, structural variants such as inversions, and/or balanced translocations may not be detected with this technology.

**SPECIAL NOTES**

For ABCC6, variants in exons 1-9 are not detected due to the presence of regions of high homology.

For CFTR, when the CFTR R117H variant is detected, reflex analysis of the polythymidine variations (5T, 7T and 9T) at the intron 9 branch/acceptor site of the CFTR gene will be performed.

For CYP21A2, targets were enriched using long-range PCR amplification, followed by next generation sequencing. Duplication analysis will only be performed and reported when c.955C>T (p.Q319\*) is detected. Sequencing and CNV analysis may have reduced sensitivity, if variants result from complex rearrangements, in trans with a gene deletion, or CYP21A2 gene duplication on one chromosome and deletion on the other chromosome. This analysis cannot detect sequencing variants located on the CYP21A2 duplicated copy.

For DDX11, only NM\_030653.3:c.1763 - 1G > C variant will be analyzed and reported.

For HBA1/HBA2, CNV analysis is offered to detect common deletions of -alpha3.7, -alpha4.2, --MED, --SEA, --FIL, --THAI, --alpha20.5, and/or HS-40.

For OTOA, variants in exons 20 - 28 are not analyzed due to high sequence homology.

For RPGRIP1L, variants in exon 23 are not detected due to assay limitation.

For SAMD9, only p.K1495E variant will be analyzed and reported.

**Friedreich Ataxia (FXN)**

The GAA repeat region of the FXN gene is assessed by trinucleotide PCR assay and capillary electrophoresis. Variances of +/-1 repeat for normal alleles and up to +/-3 repeats for premutation alleles may occur. For fully penetrant expanded alleles, the precise repeat size cannot be determined, therefore the approximate allele size is reported. Sequencing and copy number variants are analyzed by next-generation sequencing analysis.

**Friedreich Ataxia Repeat Categories**

Categories	GAA Repeat Sizes
Normal	<34
Premutation	34 - 65
Full	>65

**Spinal Muscular Atrophy (SMN1)**

The total combined copy number of SMN1 and SMN2 exon 7 is quantified based on NGS read depth. The ratio of SMN1 to SMN2 is calculated based on the read depth of a single nucleotide that distinguishes these two genes in exon 7. In addition to copy number analysis, testing for the presence or absence of a single nucleotide polymorphism (g.27134T>G in intron 7 of SMN1) associated with the presence of a SMN1 duplication allele is performed using NGS.

Ethnicity	Two SMN1 copies carrier risk before g.27134T>G testing	Carrier risk after g.27134T>G testing	
		g.27134T>G ABSENT	g.27134T>G PRESENT
Caucasian	1 in 632	1 in 769	1 in 29
Ashkenazi Jewish	1 in 350	1 in 580	LIKELY CARRIER
Asian	1 in 628	1 in 702	LIKELY CARRIER
African-American	1 in 121	1 in 396	1 in 34
Hispanic	1 in 1061	1 in 1762	1 in 140

**Variant Classification**

Only pathogenic or likely pathogenic variants are reported. Other variants including benign variants, likely benign variants, variants of uncertain significance, or inconclusive variants identified during this analysis may be reported in certain circumstances. Our laboratory's variant classification criteria are based on the ACMG and internal guidelines and our current understanding of the specific genes. This interpretation may change over time as more information about a gene and/or variant becomes available. Natera and its lab partner(s) may reclassify variants at certain intervals but may not release updated reports without a specific request made to Natera by the ordering provider. Natera may disclose incidental findings if deemed clinically pertinent to the test performed.

**Negative Results**

A negative carrier screening result reduces the risk for a patient to be a carrier of a specific disease but does not completely rule out carrier status. Please visit <https://www.natera.com/panel-option/h-all/> for a table of carrier rates, detection rates, residual risks and promised variants/exons per gene. Carrier rates before and after testing vary by ethnicity and assume a negative family history for each disease screened and the absence of clinical symptoms in the patient. Any patient with a family history for a specific genetic disease will have a higher carrier risk prior to testing and, if the disease-causing mutation in their family is not included on the test, their carrier risk would remain unchanged. Genetic counseling is recommended for patients with a family history of genetic disease so that risk figures based on actual family history can be determined and discussed along with potential implications for reproduction. Horizon carrier screening has been developed to identify the reproductive risks for monogenic inherited conditions. Even when one or both members of a couple screen negative for pathogenic variants in a specific gene, the disease risk for their offspring is not zero. There is still a low risk for the condition in their offspring due to a number of different mechanisms that are not detected by Horizon including, but not limited to, pathogenic variant(s) in the tested gene or in a different gene not included on Horizon, pathogenic variant(s) in an upstream regulator, uniparental disomy, de novo mutation(s), or digenic or polygenic inheritance.

**Additional Comments**

These analyses generally provide highly accurate information regarding the patient's carrier status. Despite this high level of accuracy, it should be kept in mind that there are many potential sources of diagnostic error, including misidentification of samples, polymorphisms, or other rare genetic variants that interfere with analysis. Families should understand that rare diagnostic errors may occur for these reasons.

Hemoglobin F	0.0		<2.0 %	
Hemoglobin A2 (Quant)	2.5		2.2-3.2 %	
Interpretation				

NORMAL PATTERN OF HEMOGLOBINS WITH LOW MCV/MCH

There is a normal pattern of hemoglobins and normal levels of Hb A2 and Hb F present. No variant hemoglobins are observed. This is consistent with A/A phenotype.

Assuming iron deficiency has been excluded, the patient could have alpha-thalassemic trait, or less likely a beta-thalassemia trait (normal Hb A2 beta-thalassemia). Alpha-thalassemia is seen in all ethnic groups but in the United States is most commonly seen in African Americans and Southeast Asians as well as people of Mediterranean, Middle Eastern and Indian subcontinent ethnicity.

If clinically indicated, testing for the seven most common alpha-thalassemia deletions is available by PCR technology. These 7 deletions are -alpha3.7, -alpha4.2, --SEA, -(alpha)20.5, --MED, --FIL and --THAI (Alpha Globin Common Mutation Analysis, TC 11175 and TC 11174 (NY clients)).

Rare variant hemoglobins have no separation from hemoglobin A by capillary zone electrophoresis or high-performance liquid chromatography. If clinically indicated, Thalassemia and Hemoglobinopathy comprehensive is available (TC 17365).

Chromosome Analysis, Blood (Continued)

Chromosome Analysis, Blood

Order ID: [REDACTED]

Specimen Type: Blood

Clinical Indication: Gamete donor

RESULT:  
NORMAL MALE KARYOTYPE

INTERPRETATION:  
Chromosome analysis revealed normal G-band patterns within the limits of standard cytogenetic analysis.

Please expect the results of any other concurrent study in a separate report.

NOMENCLATURE:  
46,XY

ASSAY INFORMATION:  
Method: G-Band (Digital Analysis: MetaSystems/Ikaros)  
Cells Counted: 20  
Band Level: 550  
Cells Analyzed: 5  
Cells Karyotyped: 3

This test does not address genetic disorders that cannot be detected by standard cytogenetic methods or rare events such as low level mosaicism or subtle rearrangements.

Steven A. Schonberg, Ph.D., FACMG, Technical Director, Cytogenetics and Genomics, 703-802-7156
