

# **Donor 7148**

# **Genetic Testing Summary**

Fairfax Cryobank recommends reviewing this genetic testing summary with your healthcare provider to determine suitability.

Last Updated: 01/13/25

Donor Reported Ancestry: French, Nigerian, Brazilian Jewish Ancestry: No

Genetic Test*	Result	Comments/Donor's Residual
		Risk**

Chromosome analysis (karyotype)	Normal male karyotype	No evidence of clinically significant chromosome abnormalities
Hemoglobin evaluation	Normal hemoglobin fractionation and MCV/MCH results	Reduced risk to be a carrier for sickle cell anemia, beta thalassemia, alpha thalassemia trait (aa/ and a-/a-) and other hemoglobinopathies
Expanded Genetic Disease Carrier Screening Panel attached- 549 diseases by gene sequencing.	Carrier: Hemochromatosis Type 2A (HFE2)  Carrier: Homocystinuria and Megaloblastic Anemia Type Cblg (MTR)  Carrier: Polycystic Kidney Disease, Autosomal Recessive (PKHD1)  Carrier: Trimethylaminuria (FMO3)  Negative for other genes sequenced.	Partner testing is recommended before using this donor.

<sup>\*</sup>No single test can screen for all genetic disorders. A negative screening result significantly reduces, but cannot eliminate, the risk for these conditions in a pregnancy.

<sup>\*\*</sup>Donor residual risk is the chance the donor is still a carrier after testing negative.

## CARRIER SCREENING REPORT

ABOUT THIS SCREEN: Horizon™ is a carrier screen for specific autosomal recessive and X-linked diseases. This information can help patients learn their risk of having a child with specific genetic conditions.

ORDER SELECTED: The Horizon Custom panel was ordered for this patient. Males are not

screened for X-linked diseases

## **FINAL RESULTS SUMMARY:**

N/A

## CARRIER for Hemochromatosis Type 2A

Positive for the likely pathogenic variant c.350\_363dup (p.Q122Tfs\*129) in the HFE2 gene. If this individual's partner is a carrier for HEMOCHROMATOSIS TYPE 2A, their chance to have a child with this condition may be as high as 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

# **CARRIER for Homocystinuria And Megaloblastic Anemia Type Cblg**

Positive for the likely pathogenic variant c.1200dup (p.V401Cfs\*19) in the MTR gene. If this individual's partner is a carrier for HOMOCYSTINURIA AND MEGALOBLASTIC ANEMIA TYPE CBLG, their chance to have a child with this condition may be as high as 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

## **CARRIER for Polycystic Kidney Disease, Autosomal Recessive**

Positive for the likely pathogenic variant c.5498C>T (p.S1833L) in the PKHD1 gene. If this individual's partner is a carrier for POLYCYSTIC KIDNEY DISEASE, AUTOSOMAL RECESSIVE, their chance to have a child with this condition may be as high as 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

## **CARRIER for Trimethylaminuria**

Positive for the pathogenic variant c.913G>T (p.E305\*) in the FMO3 gene. If this individual's partner is a carrier for TRIMETHYLAMINURIA, their chance to have a child with this condition is 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

## Negative for 545 out of 549 diseases

No other pathogenic variants were detected in the genes that were screened. The patient's remaining carrier risk after the negative screening results is listed for each disease/gene on the Horizon website at <a href="https://www.natera.com/panel-option/h-all/">https://www.natera.com/panel-option/h-all/</a>. Please see the following pages of this report for a comprehensive list of all conditions included on this individual's screen.

Carrier screening is not diagnostic and may not detect all possible pathogenic variants in a given gene.

#### RECOMMENDATIONS

Individuals who would like to review their Horizon report with a Natera Laboratory Genetic Counselor may schedule a telephone genetic information session by calling 650-249-9090 or visiting naterasession.com. Clinicians with questions may contact Natera at 650-249-9090 or email support@natera.com. Individuals with positive results may wish to discuss these results with family members to allow them the option to be screened. Comprehensive genetic counseling to discuss the implications of these test results and possible associated reproductive risk is recommended.

# **HEMOCHROMATOSIS TYPE 2A**

#### **Understanding Your Horizon Carrier Screen Results**

## What is Hemochromatosis Type 2A?

Hemochromatosis Type 2A, also called Juvenile Hemochromatosis, is an inherited iron overload disorder in which the body absorbs too much iron from food. This extra iron is stored in the organs and causes damage, especially in the liver, skin, pancreas, heart, joints, and testes. If the condition is not treated, signs and symptoms of Hemochromatosis Type 2A begin in early childhood. Too much iron in the body causes joint pain (arthritis), liver disease, diabetes, skin discoloration, excessive tiredness, and heart disease that usually becomes severe by age 30. Decreased function of the ovaries and testes, known as hypogonadism, is also common. This leads to a loss of menstrual cycles for women and a delay in puberty or lowered sex drive for men. If the condition is not treated, lifespan is shortened. Treatment with periodic blood withdrawal, which removes the excess iron, is helpful in preventing or slowing the onset and severity of symptoms but cannot reverse damage that has already occurred. Clinical trials involving potential new treatments for this condition may be available (see www.clinicaltrials.gov).

## What causes Hemochromatosis Type 2A?

Hemochromatosis Type 2A is caused by gene changes, or mutations, in both copies of the HFE2 (HJV) gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of this gene pair are not working correctly it leads to the symptoms described above. Hemochromatosis Type 2A is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the HFE2 (HJV) gene to have a child with Hemochromatosis Type 2A. People who are carriers for Hemochromatosis Type 2A are usually healthy and do not have symptoms of this condition nor do they have Hemochromatosis Type 2A themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for Hemochromatosis Type 2A there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their HFE2 (HJV) gene mutations to the child, who will then have Hemochromatosis Type 2A. Individuals found to carry more than one mutation for Hemochromatosis, Type 2A should discuss their risk for having an affected child, and any potential effects to their own health, with their health care provider.

## What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for Hemochromatosis Type 2A ordered by a health care professional. If your partner is not found to be a carrier for Hemochromatosis Type 2A, your risk of having a child with Hemochromatosis Type 2A is greatly reduced. Couples at risk of having a baby with Hemochromatosis Type 2A can opt to have prenatal diagnosis done through chorionic villus sampling (CVS) or amniocentesis during pregnancy or can choose to have the baby tested after birth for this condition. If you are not yet pregnant, your partner can have carrier screening for Hemochromatosis Type 2A ordered by a health care professional. If your partner is found to be a carrier for Hemochromatosis Type 2A you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnosis of the fetus or testing the baby after birth for Hemochromatosis Type 2A
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for Hemochromatosis Type 2A
- Adoption or use of a sperm or egg donor who is not a carrier for Hemochromatosis Type 2A

## HOMOCYSTINURIA AND MEGALOBLASTIC ANEMIA TYPE CBLG

## **Understanding Your Horizon Carrier Screen Results**

#### What does being a carrier mean?

Your results show that you are a carrier of homocystinuria and megaloblastic anemia (HCU/MA) type cblG. A carrier of a genetic condition does not have the condition. Carriers also are not certain to have a child with the condition. We are all carriers of one or more genetic conditions.

Your children are not at high risk for this condition unless your partner or donor is also a carrier of HCU/MA type cblG. Further testing can be done to see if your partner or donor is a carrier.

## What is homocystinuria and megaloblastic anemia (HCU/MA) type cbIG?

HCU/MA type cblG causes the body to be unable to break down protein properly. As a result, substances build up in the brain, causing delayed development and seizures. People with HCU/MA type cblG have difficulty growing and gaining weight. They also have megaloblastic anemia (a small number of large red blood cells). People with this condition can also have weak muscles and trouble walking. Symptoms usually start in infancy, but they can start later. Some people with this condition also have breathing or feeding problems, a small head, short stature, vision loss, and intellectual disability. Symptoms vary from person to person, with some people having more severe symptoms than others. Medical treatment can slow or stop the progress of symptoms in some people with HCU/MA cblG.<sup>1</sup>

Clinical trials involving potential new treatments for this condition could be available (see clinicaltrials.gov).

## What causes homocystinuria and megaloblastic anemia (HCU/MA) type cbIG?

HCU/MA type cblG is caused by changes, or variants, in the MTR gene. These changes make the gene not work properly. Genes are a set of instructions inside the cells of our bodies that tell our bodies how to grow and function. Everyone has two copies of the MTR gene. Carriers of HCU/MA type cblG have one working copy and one non-working copy of the gene. People with HCU/MA type cblG have no working copies of the gene.

HCU/MA type cblG is usually passed down, or inherited, from both genetic parents. We inherit one copy of the MTR gene from each of our genetic parents. When both genetic parents are carriers, each child has a 1 in 4 (25%) chance of inheriting two non-working genes and having HCU/MA type cblG. Each child also has a 1 in 2 (50%) chance of being a carrier of HCU/MA type cblG and a 1 in 4 (25%) chance of inheriting two working copies of the gene. This type of inheritance is called autosomal recessive inheritance.

## Will my children have homocystinuria and megaloblastic anemia (HCU/MA) type cbIG?

If your partner or donor also has a non-working copy of the MTR gene, your children could have HCU/MA type cblG. Each child you have together would have a 1 in 4 (25%) chance of having HCU/MA type cblG. Each child you have together would also have a 3 in 4 (75%) chance of **not** having the condition.

If your partner or donor has MTR carrier screening and no variants are found, the chance that your children would have HCU/MA type cblG is very low. No further testing would usually be needed for you, your partner or donor, or your children related to HCU/MA type cblG.

#### What can I do next?

If you want to know if your children are at risk for HCU/MA type cblG, your partner or donor would need to have MTR carrier screening. If you have questions about this testing, please ask your healthcare provider or use the resources below. Many people find it helpful to speak with a genetic counselor.

If your partner or donor is found to be an HCU/MA type cbIG carrier, your children would be at risk for having HCU/MA type cbIG.

If you or your partner or surrogate are currently pregnant, tests called CVS (chorionic villus sampling) and amniocentesis can be done during pregnancy to find out if a baby has HCU/MA type cblG. These tests both have a small risk of miscarriage. Babies can also be tested for HCU/MA type cblG after birth instead.

If you or your partner or surrogate are not yet pregnant, you could have these options:

- natural pregnancy with CVS or amniocentesis to test for HCU/MA type cblG during pregnancy;
- natural pregnancy and testing the baby after birth for HCU/MA type cblG;
- preimplantation genetic testing (PGT-M) with in vitro fertilization (IVF) to test embryos for HCU/MA type cblG;
- adoption: or
- use of a sperm or egg donor who had no variants found in MTR carrier screening.

## Where can I find more information?

- HCU Network America <u>hcunetworkamerica.org</u>
- CVS marchofdimes.org/chorionic-villus-sampling
- Amniocentesis <u>marchofdimes.org/pregnancy/amniocentesis</u>
- PGT-M <u>natera.com/womens-health/spectrum-preimplantation-genetics</u>

## What does this mean for my family?

You likely got (inherited) this non-working gene from one of your genetic parents. Your genetic siblings and other family members could also carry it. You should tell your family members about your test results so they can decide if they want carrier screening for HCU/MA type cblG.

## POLYCYSTIC KIDNEY DISEASE, AUTOSOMAL RECESSIVE

#### **Understanding Your Horizon Carrier Screen Results**

#### What is Polycystic Kidney Disease, Autosomal Recessive?

Polycystic Kidney Disease, Autosomal Recessive (ARPKD) is an inherited disorder that affects the kidneys and other organs, including the liver. Affected children are typically born with enlarged kidneys with multiple fluid-filled sacs called cysts. The kidneys do not work properly causing serious health problems. In the most severe form, the kidney problems begin in pregnancy and may affect fetal lung development because of low fluid levels in the pregnancy (oligohydramnios) caused by the fetal kidney disease. Infants born with this severe form of ARPKD often have very serious lung disease that may lead to early death. In some cases, the kidney cysts, along with progressive loss of kidney function do not develop until later infancy or childhood. Liver disease (congenital hepatic fibrosis) occurs in about half of all children with ARPKD. Currently there is no cure for this condition, although medical treatment, which may include kidney and/or liver transplantation, is available. Clinical trials involving potential new treatments for this condition may be available (see www.clinicaltrials.gov).

## What causes Polycystic Kidney Disease, Autosomal Recessive?

Polycystic Kidney Disease, Autosomal Recessive (ARPKD) is caused by a gene change, or mutation, in both copies of the PKHD1 gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of this gene do not work correctly, the kidneys do not develop properly and liver disease may also occur, leading to the symptoms described above. ARPKD is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the PKHD1 gene to have a child with ARPKD. People who are carriers for ARPKD are usually healthy and do not have symptoms nor do they have ARPKD themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for ARPKD, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their PKHD1 gene mutations to the child, who will then have the condition. Individuals found to carry more than one mutation for ARPKD should discuss their risk for having an affected child, and any potential effects to their own health, with their health care provider.

## What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for ARPKD ordered by a health care professional. If your partner is not found to be a carrier for ARPKD, your risk of having a child with ARPKD is greatly reduced. If your partner is found to be a carrier, you can opt to have prenatal diagnostic testing done through chorionic villus sampling (CVS) or amniocentesis during or can choose to have the baby tested after birth for ARPKD. If you are not yet pregnant, your partner can have carrier screening for ARPKD ordered by a health care professional. If your partner is found to be a carrier for ARPKD you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnosis of the fetus or testing the baby after birth for ARPKD
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for ARPKD
- Adoption or use of a sperm or egg donor who is not a carrier for ARPKD

## TRIMETHYLAMINURIA

#### **Understanding Your Horizon Carrier Screen Results**

## What is Trimethylaminuria?

Trimethylaminuria is an inherited condition that occurs when an enzyme in the body, called FMO3, is either missing or not working correctly. This causes a chemical called trimethylamine to build up in the body. A person with Trimethylaminuria releases excess trimethylamine, which has a strong odor, in their breath, sweat, and urine. The odor is sometimes said to smell like rotten eggs or fish. There are no other symptoms, and people with this condition do not have other health problems because of this condition, although some people have social or emotional difficulties because of the odor. Currently there is no cure for Trimethylaminuria but there are treatments that can reduce the odor. Treatments include restriction of certain foods such as milk, eggs, beans, peanuts, cruciferous vegetables, and seafood, along with use of acid soaps and lotions, antibiotics, and supplemental riboflavin. Clinical trials involving potential new treatments for this condition may be available (see <a href="https://www.clinicaltrials.gov">www.clinicaltrials.gov</a>).

## What causes Trimethylaminuria?

Trimethylaminuria is caused by a gene change, or mutation, in both copies of the FMO3 gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of this gene do not work correctly, it leads to the symptoms described above.

Trimethylaminuria is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the FMO3 gene to have a child with Trimethylaminuria. People who are carriers for Trimethylaminuria are usually healthy and do not have the condition themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for Trimethylaminuria, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their FMO3 gene mutations to the child, who will then have this condition.

Individuals found to carry more than one mutation for Trimethylaminuria should discuss their risk for having an affected child with their healthcare provider.

#### What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org).

Your siblings and other relatives have an increased chance to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves.

If you are pregnant, your partner can have carrier screening for Trimethylaminuria ordered by a healthcare professional. If your partner is not found to be a carrier, your risk of having a child with Trimethylaminuria is greatly reduced. Couples at risk of having a child with Trimethylaminuria can opt to have prenatal diagnostic testing done through chorionic villus sampling (CVS) or amniocentesis during pregnancy. They can also choose to have the baby tested after birth for this condition.

If you are not yet pregnant, your partner can have carrier screening for Trimethylaminuria ordered by a healthcare professional. If your partner is found to be a carrier, you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnostic testing of the fetus during pregnancy or testing the baby after birth for Trimethylaminuria,
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for Trimethylaminuria, or
- Adoption or use of a sperm or egg donor who is not a carrier for Trimethylaminuria.

## **VARIANT DETAILS**

Case File ID:

# FMO3, c.913G>T (p.E305\*), pathogenic

- The c.913G>T (p.E305\*) variant in the FMO3 gene has been observed at a frequency of 0.0308% in the gnomAD v2.1.1 dataset.
- This variant has been reported in a homozygous state or in conjunction with another variant in individual(s) with trimethylaminuria (PMID: 9536088).
- This premature termination variant is predicted to cause nonsense-mediated decay (NMD) in a gene where loss-of-function is a known mechanism of disease.
- This variant has been reported in ClinVar [ID: 16304].

## HFE2, c.350\_363dup (p.Q122Tfs\*129), likely pathogenic

• The c.350\_363dup (p.Q122Tfs\*129) variant in the HJV gene has not been observed in the gnomAD v2.1.1 dataset.

Report Date:

- This premature termination variant is predicted to escape nonsense-mediated decay (NMD) but impact a significant portion of the protein length or a
  critical region of the protein, potentially disrupting normal protein function.
- This variant has not been described in ClinVar.

## MTR, c.1200dup (p.V401Cfs\*19), likely pathogenic

- The c.1200dup (p.V401Cfs\*19) variant in the MTR gene has been observed at a frequency of 0.0004% in the gnomAD v2.1.1 dataset.
- This premature termination variant is predicted to cause nonsense-mediated decay (NMD) in a gene where loss-of-function is a known mechanism of disease.
- This variant has been described in ClinVar [ID: 1905103].

## PKHD1, c.5498C>T (p.S1833L), likely pathogenic

- The c.5498C>T (p.S1833L) variant in the PKHD1 gene has been observed at a frequency of 0.0156% in the gnomAD v2.1.1 dataset.
- This variant has been reported in a homozygous state or in conjunction with another variant in individual(s) with autosomal recessive polycystic kidney disease (PMID: 12846734, 19914852).
- This variant has been reported in ClinVar [ID: 496898].

## **Testing Methodology, Limitations, and Comments:**

## **Next-generation sequencing (NGS)**

Sequencing library prepared from genomic DNA isolated from a patient sample is enriched for targets of interest using standard hybridization capture protocols and PCR amplification (for targets specified below). NGS is then performed to achieve the standards of quality control metrics, including a minimum coverage of 99% of targeted regions at 20X sequencing depth. Sequencing data is aligned to human reference sequence, followed by deduplication, metric collection and variant calling (coding region +/- 20bp). Variants are then classified according to ACMGG/AMP standards of interpretation using publicly available databases including but not limited to ENSEMBL, HGMD Pro, ClinGen, ClinVar, 1000G, ESP and gnomAD. Variants predicted to be pathogenic or likely pathogenic for the specified diseases are reported. It should be noted that the data interpretation is based on our current understanding of the genes and variants at the time of reporting. Putative positive sequencing variants that do not meet internal quality standards or are within highly homologous regions are confirmed by Sanger sequencing or gene-specific long-range PCR as needed prior to reporting.

Copy Number Variant (CNV) analysis is limited to deletions involving two or more exons for all genes on the panel, in addition to specific known recurrent single-exon deletions. CNVs of small size may have reduced detection rate. This method does not detect gene inversions, single-exonic and sub-exonic deletions (unless otherwise specified), and duplications of all sizes (unless otherwise specified). Additionally, this method does not define the exact breakpoints of detected CNV events. Confirmation testing for copy number variation is performed by specific PCR, Multiplex Ligation-dependent Probe Amplification (MLPA), next generation sequencing, or other methodology.

This test may not detect certain variants due to local sequence characteristics, high/low genomic complexity, homologous sequence, or allele dropout (PCR-based assays). Variants within noncoding regions (promoter, 5'UTR, 3'UTR, deep intronic regions, unless otherwise specified), small deletions or insertions larger than 25bp, low-level mosaic variants, structural variants such as inversions, and/or balanced translocations may not be detected with this technology.

#### **SPECIAL NOTES**

For ABCC6, variants in exons 1-9 are not detected due to the presence of regions of high homology.

For CFTR, when the CFTR R117H variant is detected, reflex analysis of the polythymidine variations (5T, 7T and 9T) at the intron 9 branch/acceptor site of the CFTR gene will be performed.

For CYP21A2, targets were enriched using long-range PCR amplification, followed by next generation sequencing. Duplication analysis will only be performed and reported when c.955C>T (p.Q319\*) is detected. Sequencing and CNV analysis may have reduced sensitivity, if variants result from complex rearrangements, in trans with a gene deletion, or CYP21A2 gene duplication on one chromosome and deletion on the other chromosome. This analysis cannot detect sequencing variants located on the CYP21A2 duplicated copy.

For DDX11, only NM\_030653.3:c.1763 - 1G > C variant will be analyzed and reported.

For GJB2, CNV analysis of upstream deletions of GJB6-D13S1830 (309kb deletion) and GJB6-D13S1854 (232kb deletion) is included.

For HBA1/HBA2, CNV analysis is offered to detect common deletions of -alpha3.7, -alpha4.2, --MED, --SEA, --FIL, --THAI, --alpha20.5, and/or HS-40.

For OTOA, variants in exons 20 - 28 are not analyzed due to high sequence homology.

For RPGRIP1L, variants in exon 23 are not detected due to assay limitation.

For SAMD9, only p.K1495E variant will be analyzed and reported.

## Friedreich Ataxia (FXN)

The GAA repeat region of the FXN gene is assessed by trinucleotide PCR assay and capillary electrophoresis. Variances of +/-1 repeat for normal alleles and up to +/-3 repeats for premutation alleles may occur. For fully penetrant expanded alleles, the precise repeat size cannot be determined, therefore the approximate allele size is reported. Sequencing and copy number variants are analyzed by next-generation sequencing analysis.

## Friedreich Ataxia Repeat Categories

Categories	GAA Repeat Sizes
Normal	<34
Premutation	34 - 65
Full	>65

## Spinal Muscular Atrophy (SMN1)

The total combined copy number of SMN1 and SMN2 exon 7 is quantified based on NGS read depth. The ratio of SMN1 to SMN2 is calculated based on the read depth of a single nucleotide that distinguishes these two genes in exon 7. In addition to copy number analysis, testing for the presence or absence of a single nucleotide polymorphism (g.27134T>G in intron 7 of SMN1) associated with the presence of a SMN1 duplication allele is performed using NGS.

Ethnicity	Two SMN1 copies carrier risk before g.27134T>G testing	Carrier risk after g.27134T	sk after g.27134T>G testing	
		g.27134T>G ABSENT	g.27134T>G PRESENT	
Caucasian	1 in 632	1 in 769	1 in 29	
Ashkenazi Jewish	1 in 350	1 in 580	LIKELY CARRIER	
Asian	1 in 628	1 in 702	LIKELY CARRIER	
African-American	1 in 121	1 in 396	1 in 34	
Hispanic	1 in 1061	1 in 1762	1 in 140	

#### Variant Classification

Only pathogenic or likely pathogenic variants are reported. Other variants including benign variants, likely benign variants, variants of uncertain significance, or inconclusive variants identified during this analysis may be reported in certain circumstances. Our laboratory's variant classification criteria are based on the ACMG and internal guidelines and our current understanding of the specific genes. This interpretation may change over time as more information about a gene and/or variant becomes available. Natera and its lab partner(s) may reclassify variants at certain intervals but may not release updated reports without a specific request made to Natera by the ordering provider. Natera may disclose incidental findings if deemed clinically pertinent to the test performed.

## **Negative Results**

A negative carrier screening result reduces the risk for a patient to be a carrier of a specific disease but does not completely rule out carrier status. Please visit <a href="https://www.natera.com/panel-option/h-all/">https://www.natera.com/panel-option/h-all/</a> for a table of carrier rates, detection rates, residual risks and promised variants/exons per gene. Carrier rates before and after testing vary by ethnicity and assume a negative family history for each disease screened and the absence of clinical symptoms in the patient. Any patient with a family history for a specific genetic disease will have a higher carrier risk prior to testing and, if the disease-causing mutation in their family is not included on the test, their carrier risk would remain unchanged. Genetic counseling is recommended for patients with a family history of genetic disease so that risk figures based on actual family history can be determined and discussed along with potential implications for reproduction. Horizon carrier screening has been developed to identify the reproductive risks for monogenic inherited conditions. Even when one or both members of a couple screen negative for pathogenic variants in a specific gene, the disease risk for their offspring is not zero. There is still a low risk for the condition in their offspring due to a number of different mechanisms that are not detected by Horizon including, but not limited to, pathogenic variant(s) in the tested gene or in a different gene not included on Horizon, pathogenic variant(s) in an upstream regulator, uniparental disomy, de novo mutation(s), or digenic or polygenic inheritance.

## **Additional Comments**

These analyses generally provide highly accurate information regarding the patient's carrier status. Despite this high level of accuracy, it should be kept in mind that there are many potential sources of diagnostic error, including misidentification of samples, polymorphisms, or other rare genetic variants that interfere with analysis. Families should understand that rare diagnostic errors may occur for these reasons.

Hemoglobin F	0.0	Reference Range: <2.0 %	FINAL
Hemoglobin A2 (Quant)	2.1	Reference Range: 2.0-3.2 %	FINAL
Interpretation			FINAL

There is a normal pattern of hemoglobins and normal levels of Hb A2 and Hb F are present. No variant hemoglobins are observed. This is consistent with A/A phenotype.

If iron deficiency coexists with a mild/silent beta thalassemia trait Hb A2 may be in the normal range. Rare variant hemoglobins have no separation from hemoglobin A by capillary zone electrophoresis (CZE) or high-performance liquid chromatography (HPLC). If clinically indicated, Thalassemia and Hemoglobinopathy Comprehensive (TC 17365) should be considered.
