

Donor 7168

Genetic Testing Summary

Fairfax Cryobank recommends reviewing this genetic testing summary with your healthcare provider to determine suitability.

Last Updated: 01/24/25

Donor Reported Ancestry: Haitian Jewish Ancestry: No

| Genetic Test* | Result | Comments/Donor's Residual |
|---------------|--------|---------------------------|
| | | Risk** |

| Chromosome analysis (karyotype) | Normal male karyotype | No evidence of clinically significant chromosome abnormalities |
|---|---|---|
| Hemoglobin evaluation | Normal hemoglobin fractionation and MCV/MCH results | Reduced risk to be a carrier for sickle cell anemia, beta thalassemia, alpha thalassemia trait (aa/ and a-/a-) and other hemoglobinopathies |
| Expanded Genetic Disease Carrier Screening Panel attached- 549 diseases by gene sequencing. | Carrier: ABCA4-Related Conditions (ABCA4) Carrier: Cystic Fibrosis (CFTR) Carrier Steroid-Resistant Nephrotic Syndrome (NPHS2) Negative for other genes sequenced. | Partner testing is recommended before using this donor. |

^{*}No single test can screen for all genetic disorders. A negative screening result significantly reduces, but cannot eliminate, the risk for these conditions in a pregnancy.

^{**}Donor residual risk is the chance the donor is still a carrier after testing negative.

CARRIER SCREENING REPORT

ABOUT THIS SCREEN: Horizon™ is a carrier screen for specific autosomal recessive and X-linked diseases. This information can help patients learn their risk of having a child with specific genetic conditions.

ORDER SELECTED: The Horizon Custom panel was ordered for this patient. Males are not screened for X-linked diseases

FINAL RESULTS SUMMARY:

N/A

CARRIER for ABCA4-Related Conditions

Positive for the likely pathogenic variant c.2971G>C (p.G991R) in the ABCA4 gene. If this individual's partner is a carrier for ABCA4-RELATED CONDITIONS, their chance to have a child with this condition may be as high as 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

CARRIER for Cystic Fibrosis

Positive for the likely pathogenic variant exon 12 deletion in the CFTR gene. A small number of Cystic Fibrosis (CF) carriers may have mild respiratory or other CF-related symptoms. If this individual's partner is a carrier for Cystic Fibrosis, their chance to have a child with this condition may be as high as 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

CARRIER for Steroid-Resistant Nephrotic Syndrome

Positive for the likely pathogenic variant c.686GA (p.R229Q) in the NPHS2 gene. The c.686GA (p.R229Q) variant is a mild variant that is only expected to cause disease when found in trans with a subset of variants (PMID: 30260545, 30241959, 25349199). Homozygotes are not expected to be affected, unless present as part of a complex allele (PMID: 24509478 and 29660491). If this individual's partner is a carrier for Steroid-Resistant Nephrotic Syndrome, their chance to have a child with this condition may be as high as 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

Negative for 546 out of 549 diseases

No other pathogenic variants were detected in the genes that were screened. The patient's remaining carrier risk after the negative screening results is listed for each disease/gene on the Horizon website at https://www.natera.com/panel-option/h-all/. Please see the following pages of this report for a comprehensive list of all conditions included on this individual's screen.

Carrier screening is not diagnostic and may not detect all possible pathogenic variants in a given gene.

RECOMMENDATIONS

Individuals who would like to review their Horizon report with a Natera Laboratory Genetic Counselor may schedule a telephone genetic information session by calling 650-249-9090 or visiting naterasession.com. Clinicians with questions may contact Natera at 650-249-9090 or email support@natera.com. Individuals with positive results may wish to discuss these results with family members to allow them the option to be screened. Comprehensive genetic counseling to discuss the implications of these test results and possible associated reproductive risk is recommended.

ABCA4-RELATED CONDITIONS

Understanding Your Horizon Carrier Screen Results

What does being a carrier mean?

Your results show that you are a carrier of ABCA4-related conditions. A carrier of a genetic condition does not have the condition. Carriers also are not certain to have a child with the condition. We are all carriers of one or more genetic conditions.

Your children are not at high risk for this condition unless your partner or donor is also a carrier of ABCA4-related conditions. Further testing can be done to see if your partner or donor is a carrier.

What are ABCA4-related conditions?

ABCA4-related conditions are eye conditions that affect the retina and cause loss of vision over time. The retina is the area at the back of the eye that allows you to see. Vision loss can start between childhood and late-adulthood. People who start having vision loss earlier usually lose more vision than people who have later vision loss. ABCA4-related conditions include:

- Stargardt disease 1 (STGD1) People with STGD1 lose vision in the center of the eyes over time. They can also have increased sensitivity to light, and their eyes can take longer to adjust between light and dark. Currently, there is no treatment or cure for STGD1, but there can be ways to slow the rate of vision loss.²
- Retinitis pigmentosa (RP) People with RP often have night blindness as their first symptom. They gradually lose more vision over time, though they often will maintain their central vision.³
- Cone-rod dystrophy (CRD) CRD affects the cone and rod cells, which are the parts of the retina that help the eyes adjust vision in different levels of light and dark. People with CRD first lose sharpness in their vision and their eyes become very sensitive to light. Later, they can have color blindness and loss of peripheral (side) vision. Most people with CRD become legally blind in adulthood.⁴

Clinical trials involving potential new treatments for these conditions could be available (see clinicaltrials.gov).

What causes ABCA4-related conditions?

ABCA4-related conditions are caused by changes, or variants, in the ABCA4 gene. These changes make the gene not work properly. Genes are a set of instructions inside the cells of our bodies that tell our bodies how to grow and function. Everyone has two copies of the ABCA4 gene. Carriers of ABCA4-related conditions have one working copy and one non-working copy of the gene. People with ABCA4-related conditions have no working copies of the gene.

ABCA4-related conditions are usually passed down, or inherited, from both genetic parents. We inherit one copy of the ABCA4 gene from each of our genetic parents. When both genetic parents are carriers, each child has a 1 in 4 (25%) chance of inheriting two non-working genes and having an ABCA4-related condition. Each child also has a 1 in 2 (50%) chance of being a carrier of an ABCA4-related condition and a 1 in 4 (25%) chance of inheriting two working copies of the gene. This type of inheritance is called autosomal recessive inheritance.

Will my children have ABCA4-related conditions?

If your partner or donor also has a non-working copy of the ABCA4 gene, your children could have an ABCA4-related condition. Each child you have together would have a 1 in 4 (25%) chance of having an ABCA4-related condition. Each child you have together would also have a 3 in 4 (75%) chance of **not** having the condition.

If your partner or donor has ABCA4 carrier screening and no variants are found, the chance that your children would have an ABCA4-related condition is very low. No further testing would usually be needed for you, your partner or donor, or your children related to an ABCA4-related condition.

What can I do next?

If you want to know if your children are at risk for an ABCA4-related condition, your partner or donor would need to have ABCA4 carrier screening. If you have questions about this testing, please ask your healthcare provider or use the resources below. Many people find it helpful to speak with a genetic counselor.

If your partner or donor is found to be an ABCA4-related condition carrier, your children would be at risk for having an ABCA4-related condition.

If you or your partner or surrogate are currently pregnant, tests called CVS (chorionic villus sampling) and amniocentesis can be done during pregnancy to find out if a baby has an ABCA4-related condition. These tests both have a small risk of miscarriage. Babies can also be tested for an ABCA4-related condition after birth instead.

If you or your partner or surrogate are not yet pregnant, you could have these options:

- natural pregnancy with CVS or amniocentesis to test for an ABCA4-related condition during pregnancy;
- natural pregnancy and testing the baby after birth for an ABCA4-related condition;
- preimplantation genetic testing (PGT-M) with in vitro fertilization (IVF) to test embryos for an ABCA4-related condition;
- adoption; or
- use of a sperm or egg donor who had no variants found in ABCA4 carrier screening.

Where can I find more information?

- Foundation Fighting Blindness <u>fightingblindness.org</u>
- CVS <u>marchofdimes.org/chorionic-villus-sampling</u>
- Amniocentesis marchofdimes.org/pregnancy/amniocentesis

Clinic Information:

What does this mean for my family?

You likely got (inherited) this non-working gene from one of your genetic parents. Your genetic siblings and other family members could also carry it. You should tell your family members about your test results so they can decide if they want carrier screening for an ABCA4-related condition.

CYSTIC FIBROSIS

Understanding Your Horizon Carrier Screen Results

What are Cystic Fibrosis and CFTR-Related Disorders?

Cystic Fibrosis (CF) and CFTR-Related Disorders are inherited disorders that affect many different areas of the body including the lungs, digestive system, and fertility. CF and CFTR-Related Disorders do not affect intelligence. Signs and symptoms of CF start in early childhood and include delayed growth caused by problems in digestion and repeated lung infections that lead to permanent lung damage. Children and adults with CF usually have frequent hospitalizations because of lung infections. Over time, complications of CF can lead to lung transplants and early death. CFTR-Related Disorders cause less severe symptoms, and some only affect male fertility. There are treatments for CF that can lessen the severity of the symptoms; however, there is currently no cure. Clinical trials involving potential new treatments for this condition may be available (see www.clinicaltrials.gov).

What causes CF and CFTR-Related Disorders?

CF and CFTR-Related Disorders are caused by a change, or mutation, in both copies of the CFTR gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of this gene do not work correctly, mucus and other body fluids become thick and sticky. This causes problems with how the lungs, digestive system, and other body systems function and leads to the symptoms described above. CF and CFTR-Related Disorders are inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the CFTR gene to have a child with CF or CFTR-Related Disorders. People who are CF or CFTR-Related Disorders carriers do not have CF or CFTR-Related Disorders themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for CF and CFTR- Related Disorders, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their CFTR gene mutations to the child, who will then have CF or CFTR-Related Disorders. Although most CFTR gene mutations cause classic CF, there are some specific CFTR mutations that cause less severe symptoms, and some only affect male fertility. It is sometimes, but not always, possible to determine whether a specific CFTR mutation causes classic CF or a milder form of the condition. A small number of CF carriers may have mild respiratory or other symptoms. If you have concerns about your own health or symptoms, we encourage you to discuss your results and health history with your health care provider. Individuals found to carry more than one mutation in the CFTR genes should discuss their risk for having an affected child, and any potential effects to their own health, with their health care provider.

What can I do next?

You may wish to speak with a local genetic counselor about your CF and CFTR-Related Disorders carrier test results. A genetic counselor in your region can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for CF and CFTR-Related Disorders ordered by a health care professional. If your partner is not found to be a carrier of CF and CFTR-Related Disorders, your risk of having a child with CF and CFTR-Related Disorders is greatly reduced. Couples at risk of having a baby with CF and CFTR-Related Disorders can opt to have prenatal diagnosis done through chorionic villus sampling (CVS) or amniocentesis during pregnancy or can choose to have the baby tested after birth for CF and CFTR-Related Disorders. Although CF is screened for as part of the Newborn Screening program in some US states, babies at 25% for this condition may need diagnostic testing in addition to newborn screening. If you are not yet pregnant, your partner can have CF and CFTR-Related Disorders carrier testing ordered by a health care professional. If your partner is found to be a carrier for CF and CFTR-Related Disorders, you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnostic testing of the fetus or testing the baby after birth for CF
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for CF and CFTR-Related Disorders
- Adoption or use of a sperm or egg donor who is not a carrier for CF and CFTR-Related Disorders

STEROID-RESISTANT NEPHROTIC SYNDROME

Understanding Your Horizon Carrier Screen Results

What is Steroid-Resistant Nephrotic Syndrome?

Steroid-Resistant Nephrotic Syndrome (also known as Familial Nephrotic Syndrome or Nephrotic Syndrome, Type 2) is an inherited disorder that causes abnormal kidney function. People with this condition have large amounts of protein in their urine, low amounts of albumin (a protein in the plasma of the blood), high levels of fat in the blood, and excess fluid in body tissues (edema). Symptoms vary from person to person and usually start in infancy or childhood, although some people do not show symptoms until early adulthood. The kidney problems worsen over time, often leading to kidney failure in childhood, the teenage years, or early adulthood. Once kidney failure occurs, dialysis and then kidney transplantation are needed. Currently there is no cure for this condition and treatment is based on symptoms. Clinical trials involving potential new treatments for this condition may be available (see www.clinicaltrials.gov).

What causes Steroid-Resistant Nephrotic Syndrome?

Steroid-Resistant Nephrotic Syndrome is caused by a gene change, or mutation, in both copies of the NPHS2 gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of this gene do not work correctly, it leads to the symptoms described above. Steroid-Resistant Nephrotic Syndrome is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the NPHS2 gene to have a child with Steroid-Resistant Nephrotic Syndrome. People who are carriers for Steroid-Resistant Nephrotic Syndrome are usually healthy and do not have symptoms nor do they have Steroid-Resistant Nephrotic Syndrome themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for Steroid-Resistant Nephrotic Syndrome, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their NPHS2 gene mutations to the child, who would then have this condition. Individuals found to carry more than one mutation for Steroid-Resistant Nephrotic Syndrome should discuss any potential effects to their own health and their risk for having an affected child with their health care provider.

What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for Steroid-Resistant Nephrotic Syndrome ordered by a health care professional. If your partner is not found to be a carrier for Steroid-Resistant Nephrotic Syndrome, your risk of having a child with this condition is greatly reduced. Couples at risk of having a baby with Steroid-Resistant Nephrotic Syndrome can opt to have prenatal diagnosis done through chorionic villus sampling (CVS) or amniocentesis during pregnancy or can choose to have the baby tested after birth for this condition. If you are not yet pregnant, your partner can have carrier screening for Steroid-Resistant Nephrotic Syndrome ordered by a health care professional. If your partner is found to be a carrier for Steroid-Resistant Nephrotic Syndrome, you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnosis of the fetus or testing the baby after birth for Steroid-Resistant Nephrotic Syndrome
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for Steroid- Resistant Nephrotic Syndrome
- Adoption or use of a sperm or egg donor who is not a carrier for Steroid-Resistant Nephrotic Syndrome

VARIANT DETAILS

Date Of Birth: Case File ID:

ABCA4, c.2971G>C (p.G991R), likely pathogenic

• The c.2971G>C (p.G991R) variant in the ABCA4 gene has been observed at a frequency of 0.0718% in the gnomAD v2.1.1 dataset.

Report Date:

- This variant has been reported in a homozygous state or in conjunction with another variant in individual(s) with ABCA4-related disorders (PMID: 28044389, 11379881, 25066811, 28446513, 32278709).
- This variant has been reported in ClinVar [ID: 99182].

CFTR, exon 12 deletion, likely pathogenic

- The exon 12 deletion in the CFTR gene is predicted to result in out-of-frame changes and cause nonsense-mediated decay (NMD) in a gene where loss-of-function is a known mechanism of disease.
- This variant has been reported in a homozygous state or in conjunction with another variant in individual(s) with cystic fibrosis (PMID: 30763667, 15024729).
- This variant has not been described in ClinVar.

NPHS2, c.686G>A (p.R229Q), likely pathogenic

- The c.686G>A (p.R229Q) variant in the NPHS2 gene has been observed at a frequency of 3.0245% in the gnomAD v2.1.1 dataset.
- This variant is a mild variant that is only expected to cause disease when found in trans with a subset of variants (PMID: 30260545, 30241959, 25349199). Homozygotes are not expected to be affected, unless present as part of a complex allele (PMID: 24509478 and 29660491).
- This variant has been reported in ClinVar [ID: 5370].

Testing Methodology, Limitations, and Comments:

Next-generation sequencing (NGS)

Sequencing library prepared from genomic DNA isolated from a patient sample is enriched for targets of interest using standard hybridization capture protocols and PCR amplification (for targets specified below). NGS is then performed to achieve the standards of quality control metrics, including a minimum coverage of 99% of targeted regions at 20X sequencing depth. Sequencing data is aligned to human reference sequence, followed by deduplication, metric collection and variant calling (coding region +/- 20bp). Variants are then classified according to ACMGG/AMP standards of interpretation using publicly available databases including but not limited to ENSEMBL, HGMD Pro, ClinGen, ClinVar, 1000G, ESP and gnomAD. Variants predicted to be pathogenic or likely pathogenic for the specified diseases are reported. It should be noted that the data interpretation is based on our current understanding of the genes and variants at the time of reporting. Putative positive sequencing variants that do not meet internal quality standards or are within highly homologous regions are confirmed by Sanger sequencing or genespecific long-range PCR as needed prior to reporting.

Copy Number Variant (CNV) analysis is limited to deletions involving two or more exons for all genes on the panel, in addition to specific known recurrent singleexon deletions. CNVs of small size may have reduced detection rate. This method does not detect gene inversions, single-exonic and sub-exonic deletions (unless otherwise specified), and duplications of all sizes (unless otherwise specified). Additionally, this method does not define the exact breakpoints of detected CNV events. Confirmation testing for copy number variation is performed by specific PCR, Multiplex Ligation-dependent Probe Amplification (MLPA), next generation sequencing, or other methodology.

This test may not detect certain variants due to local sequence characteristics, high/low genomic complexity, homologous sequence, or allele dropout (PCR-based assays). Variants within noncoding regions (promoter, 5'UTR, 3'UTR, deep intronic regions, unless otherwise specified), small deletions or insertions larger than 25bp, low-level mosaic variants, structural variants such as inversions, and/or balanced translocations may not be detected with this technology.

SPECIAL NOTES

For ABCC6, sequencing variants in exons 1-7 are not detected due to the presence of regions of high homology.

For CFTR, when the CFTR R117H variant is detected, reflex analysis of the polythymidine variations (5T, 7T and 9T) at the intron 9 branch/acceptor site of the CFTR gene will be performed. Multi-exon duplication analysis is included.

For CYP21A2, targets were enriched using long-range PCR amplification, followed by next generation sequencing. Duplication analysis will only be performed and reported when c.955C>T (p.Q319*) is detected. Sequencing and CNV analysis may have reduced sensitivity, if variants result from complex rearrangements, in trans with a gene deletion, or CYP21A2 gene duplication on one chromosome and deletion on the other chromosome. This analysis cannot detect sequencing variants located on the CYP21A2 duplicated copy.

For DDX11, sequencing variants in exons 7-11 and CNV for the entire gene are not analyzed due to high sequence homology.

For GJB2, CNV analysis of upstream deletions of GJB6-D13S1830 (309kb deletion) and GJB6-D13S1854 (232kb deletion) is included.

For HBA1/HBA2, CNV analysis is offered to detect common deletions of -alpha3.7, -alpha4.2, --MED, --SEA, --FIL, --THAI, --alpha20.5, and/or HS-40.

For OTOA, sequencing variants in exons 25-29 and CNV in exons 21-29 are not analyzed due to high sequence homology.

For RPGRIP1L, variants in exon 23 are not detected due to assay limitation.

For SAMD9, only p.K1495E variant will be analyzed and reported.

Friedreich Ataxia (FXN)

The GAA repeat region of the FXN gene is assessed by trinucleotide PCR assay and capillary electrophoresis. Variances of +/-1 repeat for normal alleles and up to +/-3 repeats for premutation alleles may occur. For fully penetrant expanded alleles, the precise repeat size cannot be determined, therefore the approximate allele size is reported. Sequencing and copy number variants are analyzed by next-generation sequencing analysis.

Friedreich Ataxia Repeat Categories

| Categories | GAA Repeat Sizes |
|-------------|------------------|
| Normal | <34 |
| Premutation | 34 - 65 |
| Full | >65 |

Spinal Muscular Atrophy (SMN1)

The total combined copy number of SMN1 and SMN2 exon 7 is quantified based on NGS read depth. The ratio of SMN1 to SMN2 is calculated based on the read depth of a single nucleotide that distinguishes these two genes in exon 7. In addition to copy number analysis, testing for the presence or absence of a single

nucleotide polymorphism (g.27134T>G in intron 7 of SMN1) associated with the presence of a SMN1 duplication allele is performed using NGS.

Report Date:

| Ethnicity | Two SMN1 copies carrier risk before g.27134T>G testing | Carrier risk after g.27134T>G testing | |
|------------------|--|---------------------------------------|--------------------|
| | | g.27134T>G ABSENT | g.27134T>G PRESENT |
| Caucasian | 1 in 632 | 1 in 769 | 1 in 29 |
| Ashkenazi Jewish | 1 in 350 | 1 in 580 | LIKELY CARRIER |
| Asian | 1 in 628 | 1 in 702 | LIKELY CARRIER |
| African-American | 1 in 121 | 1 in 396 | 1 in 34 |
| Hispanic | 1 in 1061 | 1 in 1762 | 1 in 140 |

Variant Classification

Only pathogenic or likely pathogenic variants are reported. Other variants including benign variants, likely benign variants, variants of uncertain significance, or inconclusive variants identified during this analysis may be reported in certain circumstances. Our laboratory's variant classification criteria are based on the ACMG and internal guidelines and our current understanding of the specific genes. This interpretation may change over time as more information about a gene and/or variant becomes available. Natera and its lab partner(s) may reclassify variants at certain intervals but may not release updated reports without a specific request made to Natera by the ordering provider. Natera may disclose incidental findings if deemed clinically pertinent to the test performed.

Negative Results

A negative carrier screening result reduces the risk for a patient to be a carrier of a specific disease but does not completely rule out carrier status. Please visit https://www.natera.com/panel-option/h-all/ for a table of carrier rates, detection rates, residual risks and promised variants/exons per gene. Carrier rates before and after testing vary by ethnicity and assume a negative family history for each disease screened and the absence of clinical symptoms in the patient. Any patient with a family history for a specific genetic disease will have a higher carrier risk prior to testing and, if the disease-causing mutation in their family is not included on the test, their carrier risk would remain unchanged. Genetic counseling is recommended for patients with a family history of genetic disease so that risk figures based on actual family history can be determined and discussed along with potential implications for reproduction. Horizon carrier screening has been developed to identify the reproductive risks for monogenic inherited conditions. Even when one or both members of a couple screen negative for pathogenic variants in a specific gene, the disease risk for their offspring is not zero. There is still a low risk for the condition in their offspring due to a number of different mechanisms that are not detected by Horizon including, but not limited to, pathogenic variant(s) in the tested gene or in a different gene not included on Horizon, pathogenic variant(s) in an upstream regulator, uniparental disomy, de novo mutation(s), or digenic or polygenic inheritance.

Additional Comments

These analyses generally provide highly accurate information regarding the patient's carrier status. Despite this high level of accuracy, it should be kept in mind that there are many potential sources of diagnostic error, including misidentification of samples, polymorphisms, or other rare genetic variants that interfere with analysis. Families should understand that rare diagnostic errors may occur for these reasons.
