

Donor 7742

Genetic Testing Summary

Fairfax Cryobank recommends reviewing this genetic testing summary with your healthcare provider to determine suitability.

Last Updated: 03/13/25

Donor Reported Ancestry: Angolan, Nicaraguan, Honduran, Portuguese Jewish Ancestry: No

Genetic Test*	Result	Comments/Donor's Residual
		Risk**

Chromosome analysis (karyotype)	Normal male karyotype	No evidence of clinically significant chromosome abnormalities
Hemoglobin evaluation	Normal hemoglobin fractionation and MCV/MCH results	Reduced risk to be a carrier for sickle cell anemia, beta thalassemia, alpha thalassemia trait (aa/ and a-/a-) and other hemoglobinopathies
Expanded Genetic Disease Carrier Screening Panel attached- 549 diseases by gene sequencing.	Carrier: Fanconi Anemia, Group A (FANCA) Carrier: Mulibrey Nanism (TRIM37) Carrier: Pendred Syndrome (SLC26A4) Carrier: Retinitis Pigmentosa 59 (DHDDS) Carrier: Walker-Warburg Syndrome, CRPPA-Related Negative for other genes sequenced.	Partner testing is recommended before using this donor.

^{*}No single test can screen for all genetic disorders. A negative screening result significantly reduces, but cannot eliminate, the risk for these conditions in a pregnancy.

^{**}Donor residual risk is the chance the donor is still a carrier after testing negative.

CARRIER SCREENING REPORT

ABOUT THIS SCREEN: Horizon™ is a carrier screen for specific autosomal recessive and Xlinked diseases. This information can help patients learn their risk of having a child with specific genetic conditions.

ORDER SELECTED: The Horizon Custom panel was ordered for this patient. Males are not

screened for X-linked diseases

FINAL RESULTS SUMMARY:

CARRIER for Fanconi Anemia, Group A

Positive for the pathogenic variant c.416_417del (p.V139Gfs*41) in the FANCA gene. If this individual's partner is a carrier for FANCONI ANEMIA, GROUP A, their chance to have a child with this condition is 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

CARRIER for Mulibrey Nanism

Positive for the likely pathogenic variant c.2152C>T (p.Q718*) in the TRIM37 gene. If this individual's partner is a carrier for MULIBREY NANISM, their chance to have a child with this condition may be as high as 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

CARRIER for Pendred Syndrome

Positive for the pathogenic variant c.918+2T>C in the SLC26A4 gene. If this individual's partner is a carrier for PENDRED SYNDROME, their chance to have a child with this condition is 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

CARRIER for Retinitis Pigmentosa 59

Positive for the likely pathogenic variant c.886C>T (p.R296*) in the DHDDS gene. If this individual's partner is a carrier for RETINITIS PIGMENTOSA 59, their chance to have a child with this condition may be as high as 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

CARRIER for Walker-Warburg Syndrome, CRPPA-Related

Positive for the pathogenic variant c.1120-1G>T in the CRPPA gene. If this individual's partner is a carrier for WALKER-WARBURG SYNDROME, CRPPA-RELATED, their chance to have a child with this condition is 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

Negative for 544 out of 549 diseases

No other pathogenic variants were detected in the genes that were screened. The patient's remaining carrier risk after the negative screening results is listed for each disease/gene on the Horizon website at https://www.natera.com/panel-option/h-all/. Please see the following pages of this report for a comprehensive list of all conditions included on this individual's screen.

Carrier screening is not diagnostic and may not detect all possible pathogenic variants in a given gene.

RECOMMENDATIONS

Individuals who would like to review their Horizon report with a Natera Laboratory Genetic Counselor may schedule a telephone genetic information session by calling 650-249-9090 or visiting naterasession.com. Clinicians with questions may contact Natera at 650-249-9090 or email support@natera.com. Individuals with positive results may wish to discuss these results with family members to allow them the option to be screened. Comprehensive genetic counseling to discuss the implications of these test results and possible associated reproductive risk is recommended.

FANCONI ANEMIA, GROUP A

Understanding Your Horizon Carrier Screen Results

What is Fanconi Anemia, Group A?

Fanconi Anemia, Group A is an inherited disorder that causes bone marrow failure, increased risk for cancer, and physical findings such as irregular skin coloring, malformed thumbs or forearms, short stature, kidney/urinary problems, and heart defects. In some cases, affected individuals have been treated with stem cell transplantation from cord blood or bone marrow. Couples at risk of having an affected child may consider cord blood banking, as siblings have a higher chance of being a match for stem cell transplantation than a non-related individual. More information can be found at: https://parentsguidecordblood.org/en. Clinical trials involving potential new treatments for this condition may be available (see www.clinicaltrials.gov).

What causes Fanconi Anemia, Group A?

Fanconi Anemia, Group A is caused by a gene change, or mutation in both copies of the FANCA gene pair. These mutations cause the genes to not work properly or not work at all. The job of the FANCA genes is to help repair DNA within cells. When both copies of this gene pair do not work correctly, it can cause cell death and/or uncontrolled cell growth which leads to the symptoms described above. Fanconi Anemia, Group A is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the FANCA gene to have a child with Fanconi Anemia, Group A. People who are carriers for Fanconi Anemia, Group A, are usually healthy and do not have symptoms nor do they have Fanconi Anemia themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for Fanconi Anemia, Group A, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their FANCA gene mutations to the child, who will then have this condition. Individuals found to carry more than one mutation for Fanconi Anemia, Group A should discuss their risk for having an affected child, and any potential effects to their own health, with their health care provider. There are a number of other forms of Fanconi Anemia, each caused by mutations in different genes. A person who is a carrier for Fanconi Anemia, Group A is not likely to be at increased risk for having a child with these other forms of Fanconi Anemia.

What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for Fanconi Anemia, Group A ordered by a health care professional. If your partner is not found to be a carrier for Fanconi Anemia, Group A, your risk of having a child with Fanconi Anemia is greatly reduced. Couples at risk of having a baby with Fanconi Anemia, Group A can opt to have prenatal diagnosis done through chorionic villus sampling (CVS) or amniocentesis during pregnancy or can choose to have the baby tested after birth for this condition. If you are not yet pregnant, your partner can have carrier screening for Fanconi Anemia, Group A ordered by a health care professional. If your partner is found to be a carrier for Fanconi Anemia, Group A, you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnosis of the fetus or testing the baby after birth for Fanconi Anemia, Group A
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for Fanconi Anemia, Group A
- Adoption or use of a sperm or egg donor who is not a carrier for Fanconi Anemia, Group A

- Fanconi Anemia Research Fund, Inc.: www.fanconi.org
- Prenatal diagnosis done through CVS: http://www.marchofdimes.org/chorionic-villus-sampling.aspx
- Prenatal diagnosis done through Amniocentesis: http://www.marchofdimes.org/amniocentesis.aspx
- PGD with IVF: http://www.natera.com/spectrum

MULIBREY NANISM

Understanding Your Horizon Carrier Screen Results

What is Mulibrey Nanism?

Mulibrey Nanism is an inherited disorder that causes severe growth problems and affects many parts of the body. Mulibrey stands for †Muscle, Liver, Brain, and Eyes†and nanism means dwarfism. In this disorder, growth delays start during pregnancy and worsen with time leading to very short stature. Other common symptoms can include weak muscle tone (hypotonia), enlarged liver and spleen, heart problems, diabetes, various eye problems, intellectual disability, and distinctive facial features. Some affected children also have lung problems, discolorations of their skin (acanthosis nigricans), underdeveloped genitals, and/or bone problems, and some develop a type of kidney cancer called †Wilms tumorâ€. Currently there is no cure for Mulibrey Nanism and treatment is based on symptoms. Clinical trials involving potential new treatments for this disorder may be available (see www.clinicaltrials.gov).

What causes Mulibrey Nanism?

Mulibrey Nanism is caused by changes, or mutations, in both copies of the TRIM37 gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of the TRIM37 gene are not working correctly it leads to the symptoms described above. Mulibrey Nanism is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the TRIM37 gene to have a child with Mulibrey Nanism. People who are carriers for Mulibrey Nanism are usually healthy and do not have symptoms, nor do they have the disorder themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for Mulibrey Nanism, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their TRIM37 gene mutations to the child, who will then have this disorder. Individuals found to carry more than one mutation for Mulibrey Nanism should discuss their risk for having an affected child with their health care provider.

PENDRED SYNDROME

Understanding Your Horizon Carrier Screen Results

What is Pendred Syndrome?

Pendred Syndrome is an inherited disorder that causes hearing loss and growths on the thyroid gland called goiters. Most children with Pendred Syndrome are either born with or develop sudden, severe hearing loss by age 3. Enlargement of the thyroid glands (goiters) may develop in late childhood or early adulthood. Some people with Pendred Syndrome who have goiters have low thyroid function and need medication, but most do not. Other symptoms of Pendred Syndrome may include difficulties with balance or other inner ear abnormalities. Some children have a slightly different form of this disorder, sometimes called DFNB4, which includes hearing loss, balance problems, and inner ear abnormalities, but no thyroid goiters. It is sometimes, but not always, possible to determine whether a specific mutation in the SLC26A4 gene will cause Pendred Syndrome or DFNB4. Currently, there is no cure for this disorder and treatment is based on symptoms. Clinical trials involving potential new treatments for these conditions may be available (see www.clinicaltrials.gov).

What causes Pendred Syndrome?

Pendred Syndrome is caused by a gene change, or mutation, in both copies of the SLC26A4 gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of the SLC26A4 gene do not work properly, it leads to the symptoms described above. Pendred Syndrome is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the SLC26A4 gene to have a child with Pendred Syndrome. People who are carriers for Pendred Syndrome are usually healthy and do not have symptoms nor do they have Pendred Syndrome themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for Pendred Syndrome, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their SLC26A4 gene mutations to the child, who will then have this condition. Individuals found to carry more than one mutation for Pendred Syndrome should discuss their risk for having an affected child with their health care provider.

RETINITIS PIGMENTOSA 59

Understanding Your Horizon Carrier Screen Results

What is Retinitis Pigmentosa 59?

Retinitis Pigmentosa 59 is one of a group of inherited eye disorders in which the retina, the area at the back of the eye that allows you to see, gradually stops working. Retinitis Pigmentosa 59 causes progressive vision loss. The age at which symptoms begin and the severity of the condition varies from person to person. The first symptom is usually loss of night vision. Over time, loss of peripheral vision (tunnel vision) develops. Then, loss of central vision occurs. Retinitis Pigmentosa 59 affects only the vision. Currently there is no cure or specific treatment to prevent the vision loss. Clinical trials involving potential new treatments for this condition may be available (see www.clinicaltrials.gov).

What causes Retinitis Pigmentosa 59?

Retinitis Pigmentosa (RP) can be caused by mutations in one of a number of different genes with different inheritance patterns. Retinitis Pigmentosa 59 is caused by a gene change, or mutation, in both copies of the DHDDS gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of this gene do not work correctly, it results in the progressive vision loss described above. Retinitis Pigmentosa 59 is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the DHDDS gene to have a child with Retinitis Pigmentosa 59. People who are carriers for Retinitis Pigmentosa 59 are usually healthy and do not have symptoms nor do they have Retinitis Pigmentosa themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for Retinitis Pigmentosa 59, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their DHDDS gene mutations to the child, who will then have this condition. Individuals found to carry more than one mutation for Retinitis Pigmentosa 59 should discuss any potential effects to their own vision and their risk for having an affected child with their health care provider.

What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for Retinitis Pigmentosa 59 ordered by a health care professional. If your partner is not found to be a carrier for Retinitis Pigmentosa 59, your risk of having a child with Retinitis Pigmentosa 59 is greatly reduced. Couples at risk of having a baby with Retinitis Pigmentosa 59, can opt to have prenatal diagnosis done through chorionic villus sampling (CVS) or amniocentesis during pregnancy or can choose to have the baby tested after birth for this condition. If you are not yet pregnant, your partner can have carrier screening for Retinitis Pigmentosa 59 ordered by a health care professional. If your partner is found to be a carrier for Retinitis Pigmentosa 59, you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnosis of the fetus or testing the baby after birth for Retinitis Pigmentosa 59
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for Retinitis Pigmentosa 59

WALKER-WARBURG SYNDROME, CRPPA-RELATED

Understanding Your Horizon Carrier Screen Results

What is Walker-Warburg Syndrome, CRPPA-Related?

Walker-Warburg Syndrome, CRPPA-Related is an inherited disorder that affects many parts of the body, especially the brain, eyes, and muscles. Signs and symptoms are often present before birth but sometimes start in infancy and include weak muscle tone (hypotonia), excess fluid on the brain (hydrocephalus), severe brain abnormalities, and eye defects with vision problems. Infants and children with Walker-Warburg Syndrome, CRPPA-Related have worsening muscle weakness, problems with movement and coordination, seizures, and severe developmental delay with intellectual disability. Although symptoms vary from person to person, lifespan is usually shortened with death often occurring in early childhood. Currently, there is no cure or specific treatment for this disorder. Clinical trials involving potential new treatments for this condition may be available (see www.clinicaltrials.gov). Rarely, mutations in the same gene pair cause a related condition called Limb-Girdle Muscular Dystrophy, Type 2U. Limb-Girdle Muscular Dystrophy, Type 2U causes severe muscle weakness in the shoulder and hip areas along with muscle pain during exertion that usually starts in childhood. The information below is about Walker-Warburg Syndrome, CRPPA-Related, the more common condition. However, the inheritance pattern and reproductive options listed below apply to Limb-Girdle Muscular Dystrophy, Type 2U as well.

What causes Walker-Warburg Syndrome, CRPPA-Related?

Walker-Warburg Syndrome, CRPPA-Related is caused by a change, or mutation, in both copies of the CRPPA (ISPD) gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of the CRPPA (ISPD) gene do not work correctly, it leads to the symptoms described above. It is sometimes, but not always, possible to determine whether a specific mutation in the CRPPA (ISPD) gene will cause Walker-Warburg Syndrome, CRPPA-Related or Limb-Girdle Muscular Dystrophy, Type 2U. Walker-Warburg Syndrome, CRPPA-Related is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the CRPPA (ISPD) gene to have a child with Walker-Warburg Syndrome, CRPPA-Related. People who are carriers for Walker-Warburg Syndrome, CRPPA-Related are usually healthy and do not have symptoms, nor do they have the disorder themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for Walker-Warburg Syndrome, CRPPA-Related or related condition there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their CRPPA (ISPD) gene mutations to the child, who will then have this disorder. Individuals found to carry more than one mutation for Walker-Warburg Syndrome, CRPPA-Related should discuss their risk for having an affected child and any potential effects to their own health with their health care provider. There are a number of other forms of Walker-Warburg Syndrome and Limb-Girdle Muscular Dystrophy, each caused by mutations in different genes. A person who carries a mutation in the CRPPA gene is not likely to be at increased risk for having children with the other forms of these disorders.

What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for Walker-Warburg Syndrome, CRPPA-Related ordered by a health care professional. If your partner is not found to be a carrier for Walker-Warburg Syndrome, CRPPA-Related, your risk of having an affected child is greatly reduced. Couples at risk of having a baby with Walker-Warburg Syndrome, CRPPA-Related can opt to have prenatal diagnosis done through chorionic villus sampling (CVS) or amniocentesis during pregnancy or can choose to have the baby tested after birth for this condition. If you are not yet pregnant, your partner can have carrier screening for Walker-Warburg Syndrome, CRPPA-Related ordered by a health care professional. If your partner is found to be a carrier for Walker-Warburg Syndrome, you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnosis of the fetus or testing the baby after birth for Walker-Warburg Syndrome, CRPPA-Related or related disorder
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for Walker-Warburg Syndrome, CRPPA-Related or related disorder
- · Adoption or use of a sperm or egg donor who is not a carrier for Walker-Warburg Syndrome, CRPPA-Related or related disorder

- Genetics Home Reference: http://ghr.nlm.nih.gov/condition/walker-warburg-syndrome

VARIANT DETAILS

CRPPA, c.1120-1G>T, pathogenic

- The c.1120-1G>T variant in the CRPPA gene has not been observed in the gnomAD v2.1.1 dataset.
- This variant has been reported in a homozygous state or in conjunction with another variant in individual(s) with muscular dystrophy-dystroglycanopathy, type A, 7 (PMID: 22522420).
- Functional studies demonstrated that this variant causes reduced protein activity (PMID: 22522420).
- This canonical splicing variant is predicted to maintain the reading frame but disrupt a significant percentage of the protein length or a critical region of the protein, potentially disrupting normal protein function.
- This variant has been reported in ClinVar [ID: 31561].

DHDDS, c.886C>T (p.R296*), likely pathogenic

- The c.886C>T (p.R296*) variant in the DHDDS gene has not been observed in the gnomAD v2.1.1 dataset.
- This premature termination variant is predicted to escape nonsense-mediated decay (NMD) but impact a significant portion of the protein length or a critical region of the protein, potentially disrupting normal protein function.
- This variant has been described in ClinVar [ID: 2051697].

FANCA, c.416_417del (p.V139Gfs*41), pathogenic

- The c.416_417del (p.V139Gfs*41) variant in the FANCA gene has not been observed in the gnomAD v2.1.1 dataset.
- This premature termination variant is predicted to cause nonsense-mediated decay (NMD) in a gene where loss-of-function is a known mechanism of disease.
- This variant has been reported in ClinVar [ID: 219633].

SLC26A4, c.918+2T>C, pathogenic

- The c.918+2T>C variant in the SLC26A4 gene has been observed at a frequency of 0.0011% in the gnomAD v2.1.1 dataset.
- This variant has been reported in a homozygous state or in conjunction with another variant in individual(s) with Pendred syndrome (PMID: 23918157).
- This canonical splicing variant is predicted to maintain the reading frame but disrupt a significant percentage of the protein length or a critical region of the protein, potentially disrupting normal protein function.
- This variant has been reported in ClinVar [ID: 370108].

TRIM37, c.2152C>T (p.Q718*), likely pathogenic

- The c.2152C>T (p.Q718*) variant in the TRIM37 gene has not been observed in the gnomAD v2.1.1 dataset.
- This premature termination variant is predicted to cause nonsense-mediated decay (NMD) in a gene where loss-of-function is a known mechanism of disease.
- This variant has not been described in ClinVar.

Testing Methodology, Limitations, and Comments:

Next-generation sequencing (NGS)

Sequencing library prepared from genomic DNA isolated from a patient sample is enriched for targets of interest using standard hybridization capture protocols and PCR amplification (for targets specified below). NGS is then performed to achieve the standards of quality control metrics, including a minimum coverage of 99% of targeted regions at 20X sequencing depth. Sequencing data is aligned to human reference sequence, followed by deduplication, metric collection and variant calling (coding region +/- 20bp). Variants are then classified according to ACMGG/AMP standards of interpretation using publicly available databases including but not limited to ENSEMBL, HGMD Pro, ClinGen, ClinVar, 1000G, ESP and gnomAD. Variants predicted to be pathogenic or likely pathogenic for the specified diseases are reported. It should be noted that the data interpretation is based on our current understanding of the genes and variants at the time of reporting. Putative positive sequencing variants that do not meet internal quality standards or are within highly homologous regions are confirmed by Sanger sequencing or gene-specific long-range PCR as needed prior to reporting.

Copy Number Variant (CNV) analysis is limited to deletions involving two or more exons for all genes on the panel, in addition to specific known recurrent single-exon deletions. CNVs of small size may have reduced detection rate. This method does not detect gene inversions, single-exonic and sub-exonic deletions (unless otherwise specified), and duplications of all sizes (unless otherwise specified). Additionally, this method does not define the exact breakpoints of detected CNV events. Confirmation testing for copy number variation is performed by specific PCR, Multiplex Ligation-dependent Probe Amplification (MLPA), next generation sequencing, or other methodology.

This test may not detect certain variants due to local sequence characteristics, high/low genomic complexity, homologous sequence, or allele dropout (PCR-based assays). Variants within noncoding regions (promoter, 5'UTR, 3'UTR, deep intronic regions, unless otherwise specified), small deletions or insertions larger than 25bp, low-level mosaic variants, structural variants such as inversions, and/or balanced translocations may not be detected with this technology.

SPECIAL NOTES

For ABCC6, sequencing variants in exons 1-7 are not detected due to the presence of regions of high homology.

For CFTR, when the CFTR R117H variant is detected, reflex analysis of the polythymidine variations (5T, 7T and 9T) at the intron 9 branch/acceptor site of the CFTR gene will be performed. Multi-exon duplication analysis is included.

For CYP21A2, targets were enriched using long-range PCR amplification, followed by next generation sequencing. Duplication analysis will only be performed and reported when c.955C>T (p.Q319*) is detected. Sequencing and CNV analysis may have reduced sensitivity, if variants result from complex rearrangements, in trans with a gene deletion, or CYP21A2 gene duplication on one chromosome and deletion on the other chromosome. This analysis cannot detect sequencing variants located on the CYP21A2 duplicated copy.

For DDX11, sequencing variants in exons 7-11 and CNV for the entire gene are not analyzed due to high sequence homology.

For GJB2, CNV analysis of upstream deletions of GJB6-D13S1830 (309kb deletion) and GJB6-D13S1854 (232kb deletion) is included.

For HBA1/HBA2, CNV analysis is offered to detect common deletions of -alpha3.7, -alpha4.2, --MED, --SEA, --FIL, --THAI, --alpha20.5, and/or HS-40.

For OTOA, sequencing variants in exons 25-29 and CNV in exons 21-29 are not analyzed due to high sequence homology.

For RPGRIP1L, variants in exon 23 are not detected due to assay limitation.

For SAMD9, only p.K1495E variant will be analyzed and reported.

Friedreich Ataxia (FXN)

The GAA repeat region of the FXN gene is assessed by trinucleotide PCR assay and capillary electrophoresis. Variances of +/-1 repeat for normal alleles and up to +/-3 repeats for premutation alleles may occur. For fully penetrant expanded alleles, the precise repeat size cannot be determined, therefore the approximate allele size is reported. Sequencing and copy number variants are analyzed by next-generation sequencing analysis.

Friedreich Ataxia Repeat Categories

Categories	GAA Repeat Sizes
Normal	<34
Premutation	34 - 65
Full	>65

Spinal Muscular Atrophy (SMN1)

The total combined copy number of SMN1 and SMN2 exon 7 is quantified based on NGS read depth. The ratio of SMN1 to SMN2 is calculated based on the read depth of a single nucleotide that distinguishes these two genes in exon 7. In addition to copy number analysis, testing for the presence or absence of a single nucleotide polymorphism (g.27134T>G in intron 7 of SMN1) associated with the presence of a SMN1 duplication allele is performed using NGS.

thnicity Tv	Two SMN1 copies carrier risk before g.27134T>G testing	Carrier risk after g.27134T>G testing	
		g.27134T>G ABSENT	g.27134T>G PRESENT
Caucasian	1 in 632	1 in 769	1 in 29
Ashkenazi Jewish	1 in 350	1 in 580	LIKELY CARRIER
Asian	1 in 628	1 in 702	LIKELY CARRIER
African-American	1 in 121	1 in 396	1 in 34
Hispanic	1 in 1061	1 in 1762	1 in 140

Variant Classification

Only pathogenic or likely pathogenic variants are reported. Other variants including benign variants, likely benign variants, variants of uncertain significance, or inconclusive variants identified during this analysis may be reported in certain circumstances. Our laboratory's variant classification criteria are based on the ACMG and internal guidelines and our current understanding of the specific genes. This interpretation may change over time as more information about a gene and/or variant becomes available. Natera and its lab partner(s) may reclassify variants at certain intervals but may not release updated reports without a specific request made to Natera by the ordering provider. Natera may disclose incidental findings if deemed clinically pertinent to the test performed.

Negative Results

A negative carrier screening result reduces the risk for a patient to be a carrier of a specific disease but does not completely rule out carrier status. Please visit https://www.natera.com/panel-option/h-all/ for a table of carrier rates, detection rates, residual risks and promised variants/exons per gene. Carrier rates before and after testing vary by ethnicity and assume a negative family history for each disease screened and the absence of clinical symptoms in the patient. Any patient with a family history for a specific genetic disease will have a higher carrier risk prior to testing and, if the disease-causing mutation in their family is not included on the test, their carrier risk would remain unchanged. Genetic counseling is recommended for patients with a family history of genetic disease so that risk figures based on actual family history can be determined and discussed along with potential implications for reproduction. Horizon carrier screening has been developed to identify the reproductive risks for monogenic inherited conditions. Even when one or both members of a couple screen negative for pathogenic variants in a specific gene, the disease risk for their offspring is not zero. There is still a low risk for the condition in their offspring due to a number of different mechanisms that are not detected by Horizon including, but not limited to, pathogenic variant(s) in the tested gene or in a different gene not included on Horizon, pathogenic variant(s) in an upstream regulator, uniparental disomy, de novo mutation(s), or digenic or polygenic inheritance.

Additional Comments

These analyses generally provide highly accurate information regarding the patient's carrier status. Despite this high level of accuracy, it should be kept in mind that there are many potential sources of diagnostic error, including misidentification of samples, polymorphisms, or other rare genetic variants that interfere with analysis. Families should understand that rare diagnostic errors may occur for these reasons.
