

CDEDNA DONOR CENETIC TECTING CHANAARY

SPERM DONOR GENETIC TESTING SUMMARY Donor # 7739

Fairfax Cryobank recommends reviewing this genetic testing summary with your healthcare provider to determine suitability.

Last Updated: 04/09/2025

Donor Reported Ancestry: Chinese Jewish Ancestry: No

Genetic Test*	Result	Comments
		Donor's Residual Risk**
Chromosome analysis (karyotype)	Normal male karyotype	No evidence of clinically significant chromosome abnormalities
Hemoglobin evaluation	Normal hemoglobin fractionation and MCV/MCH results	Reduced risk to be a carrier for sickle cell anemia, beta thalassemia, alpha thalassemia trait (aa/ and a-/a-) and other hemoglobinopathies
Expanded Genetic Disease Carrier Screening Panel attached - 549 diseases by gene sequencing and del/dup analysis.	Carrier: Congenital disorder of glycosylation, type 1A, PMM2-related (PMM2) Carrier: Congenital secretory chloride	Partner testing is recommended before using this donor.
	diarrhea 1 (SLC26A3) Negative for other genes tested.	

^{*}No single test can screen for all genetic disorders. A negative screening result significantly reduces, but cannot eliminate, the risk for these conditions in a pregnancy.

^{**}Donor residual risk is the chance the donor is still a carrier after testing negative.

CARRIER SCREENING REPORT

ABOUT THIS SCREEN: Horizon™ is a carrier screen for specific autosomal recessive and Xlinked diseases. This information can help patients learn their risk of having a child with specific genetic conditions.

ORDER SELECTED: The Horizon Custom

panel was ordered for this patient. Males are not

screened for X-linked diseases

FINAL RESULTS SUMMARY:

CARRIER for CONGENITAL DISORDER OF GLYCOSYLATION, TYPE 1A, PMM2-Related

Positive for the likely pathogenic variant c.289C>T (p.Q97*) in the PMM2 gene. If this individual's partner is a carrier for CONGENITAL DISORDER OF GLYCOSYLATION, TYPE 1A, PMM2-Related, their chance to have a child with this condition may be as high as 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

CARRIER for Congenital Secretory Chloride Diarrhea 1

Positive for the pathogenic variant c.269_270dup (p.G91Kfs*3) in the SLC26A3 gene. If this individual's partner is a carrier for CONGENITAL SECRETORY CHLORIDE DIARRHEA 1, their chance to have a child with this condition is 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

Negative for 547 out of 549 diseases

No other pathogenic variants were detected in the genes that were screened. The patient's remaining carrier risk after the negative screening results is listed for each disease/gene on the Horizon website at https://www.natera.com/panel-option/h-all/. Please see the following pages of this report for a comprehensive list of all conditions included on this individual's screen.

Carrier screening is not diagnostic and may not detect all possible pathogenic variants in a given gene.

RECOMMENDATIONS

Individuals who would like to review their Horizon report with a Natera Laboratory Genetic Counselor may schedule a telephone genetic information session by calling 650-249-9090 or visiting naterasession.com. Clinicians with questions may contact Natera at 650-249-9090 or email support@natera.com. Individuals with positive results may wish to discuss these results with family members to allow them the option to be screened. Comprehensive genetic counseling to discuss the implications of these test results and possible associated reproductive risk is recommended.

CONGENITAL DISORDER OF GLYCOSYLATION, TYPE 1A, PMM2-Related

Understanding Your Horizon Carrier Screen Results

What is Congenital Disorder of Glycosylation, Type 1A, PMM2-Related?

Congenital Disorder of Glycosylation, Type 1A, PMM2-Related (CDG-1A), also known as PMM2- Congenital Disorder of Glycosylation, is an inherited disorder that affects many parts of the body. There are three forms of this condition: the infantile multisystem type, the late-infantile and childhood ataxia- intellectual disability type, and the adult stable disability type. Signs and symptoms of the infantile multisystem type usually begin in infancy and include weak muscle tone, inverted nipples, abnormal distribution of fat, eyes that do not look in the same direction (strabismus), distinct facial features, developmental delay, failure to grow or gain weight, and childhood-onset vision loss. Children with this early type of CDG-1A may also have an underdeveloped area of the brain, called the cerebellum, which controls and coordinates body movement. They may also have elevated liver function tests, seizures, fluid around the heart, and/or blood clotting disorders. The symptoms associated with the infantile form of CDG-1A can be life-threatening and about 20% of affected infants die within the first year of life. Children with the late-infantile and childhood ataxia-intellectual disability type of CDG-1A develop symptoms between 3 and 10 years, which often include seizures, weak muscle tone, delayed language, inability to walk, vision loss, contractions of the joints, bone deformities, and intellectual disability. Some children may also experience stroke-like episodes. Teenagers and adults with the adult stable disability type of CDG-1A may have reduced sensation and weakness in their arms and legs, an abnormal curvature of the spine, premature aging, and increased risk for blood clots. Females with this form of CDG-1A typically do not go through puberty. Currently there is no cure for any form of this disorder and treatment is based on symptoms. Clinical trials involving potential new treatments for this condition may be available (see www.clinicaltrials.gov).

What causes Congenital Disorder of Glycosylation, Type 1A, PMM2-Related?

CDG-1A is caused by a change, or mutation, in both copies of the PMM2 gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of this gene do not work correctly, it leads to the symptoms described above. CDG-1A is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of their PMM2 gene to have a child with CDG-1A. People who are carriers for CDG-1A are usually healthy and do not have symptoms nor do they have CDG-1A themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for CDG-1A there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their PMM2 gene mutations to the child, who will then have the condition. Individuals found to carry more than one mutation for CDG-1A should discuss their risk for having an affected child with their health care provider. There are other forms of Congenital Disorder of Glycosylation, each caused by mutations in different genes. A person who carries a mutation in the PMM2 gene is not likely to be at increased risk for having children with these other forms.

What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for CDG-1A ordered by a health care professional. If your partner is not found to be a carrier for CDG-1A, your risk of having a child with CDG-1A is greatly reduced. Couples at risk of having a baby with CDG-1A can opt to have prenatal diagnosis done through chorionic villus sampling (CVS) or amniocentesis during pregnancy or can choose to have the baby tested after birth for this condition. If you are not yet pregnant, your partner can have carrier screening for CDG-1A ordered by a health care professional. If your partner is found to be a carrier for CDG-1A, you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnostic testing of the fetus or testing the baby after birth for CDG-1A
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for CDG-1A
- Adoption or use of a sperm or egg donor who is not a carrier for CDG-1A

CONGENITAL SECRETORY CHLORIDE DIARRHEA 1

Understanding Your Horizon Carrier Screen Results

What does being a carrier mean?

Your results show that you are a carrier of congenital secretory chloride diarrhea 1 (CCD). A carrier of a genetic condition does not have the condition. Carriers also are not certain to have a child with the condition. We are all carriers of one or more genetic conditions.

Your children are not at high risk for this condition unless your partner or donor is also a carrier of CCD. Further testing can be done to see if your partner or donor is a carrier.

What is congenital secretory chloride diarrhea 1 (CCD)?

CCD causes people to lose too much water and chloride in their stool (diarrhea). Chloride is a mineral that works with other chemicals in the body to help the body function properly. When the body loses too much water and chloride, the levels of other important chemicals (like sodium and potassium) can also become abnormal. This is called electrolyte imbalance, which can cause metabolic alkalosis. People with metabolic alkalosis can have fatigue, irritability, muscle cramps, confusion, abnormal heart rhythm, seizures, and coma. People with CCD can also have dehydration, delayed growth, and kidney disease. Babies with CCD can have polyhydramnios (extra amniotic fluid) and larger intestines seen on prenatal ultrasound. Babies with CCD can also be born early (premature) and have a swollen belly at birth. Currently, there is no cure for the condition, but people with CCD can take chloride, sodium, and potassium supplements to help with the electrolyte imbalance. 12.3

Clinical trials involving potential new treatments for this condition could be available (see clinicaltrials.gov).

What causes congenital secretory chloride diarrhea 1 (CCD)?

CCD is caused by changes, or variants, in the SLC26A3 gene. These changes make the gene not work properly. Genes are a set of instructions inside the cells of our bodies that tell our bodies how to grow and function. Everyone has two copies of the SLC26A3 gene. Carriers of CCD have one working copy and one non-working copy of the gene. People with CCD have no working copies of the gene.

CCD is usually passed down, or inherited, from both genetic parents. We inherit one copy of the SLC26A3 gene from each of our genetic parents. When both genetic parents are carriers, each child has a 1 in 4 (25%) chance of inheriting two non-working genes and having CCD. Each child also has a 1 in 2 (50%) chance of being a carrier of CCD and a 1 in 4 (25%) chance of inheriting two working copies of the gene. This type of inheritance is called autosomal recessive inheritance.

Will my children have congenital secretory chloride diarrhea 1 (CCD)?

If your partner or donor also has a non-working copy of the SLC26A3 gene, your children could have CCD. Each child you have together would have a 1 in 4 (25%) chance of having CCD. Each child you have together would also have a 3 in 4 (75%) chance of **not** having the condition.

If your partner or donor has SLC26A3 carrier screening and no variants are found, the chance that your children would have CCD is very low. No further testing would usually be needed for you, your partner or donor, or your children related to CCD.

What can I do next?

If you want to know if your children are at risk for CCD, your partner or donor would need to have SLC26A3 carrier screening. If you have questions about this testing, please ask your healthcare provider or use the resources below. Many people find it helpful to speak with a genetic counselor.

If your partner or donor is found to be a CCD carrier, your children would be at risk for having CCD.

If you or your partner or surrogate are currently pregnant, tests called CVS (chorionic villus sampling) and amniocentesis can be done during pregnancy to find out if a baby has CCD. These tests both have a small risk of miscarriage. Babies can also be tested for CCD after birth instead.

If you or your partner or surrogate are not yet pregnant, you could have these options:

- natural pregnancy with CVS or amniocentesis to test for CCD during pregnancy;
- natural pregnancy and testing the baby after birth for CCD;
- preimplantation genetic testing (PGT-M) with in vitro fertilization (IVF) to test embryos for CCD;
- adoption; or
- use of a sperm or egg donor who had no variants found in SLC26A3 carrier screening.

Where can I find more information?

- Genetic and Rare Diseases Information Center <u>rarediseases.info.nih.gov/diseases/10001/congenital-chloride-diarrhea</u>
- CVS marchofdimes.org/chorionic-villus-sampling
- Amniocentesis marchofdimes.org/pregnancy/amniocentesis
- PGT-M <u>natera.com/womens-health/spectrum-preimplantation-genetics</u>

What does this mean for my family?

You likely got (inherited) this non-working gene from one of your genetic parents. Your genetic siblings and other family members could also carry it. You should tell your family members about your test results so they can decide if they want carrier screening for CCD.

VARIANT DETAILS

PMM2, c.289C>T (p.Q97*), likely pathogenic

- The c.289C>T (p.Q97*) variant in the PMM2 gene has not been observed in the gnomAD v2.1.1 dataset.
- This premature termination variant is predicted to cause nonsense-mediated decay (NMD) in a gene where loss-of-function is a known mechanism of disease.
- This variant has not been described in ClinVar.

SLC26A3, c.269_270dup (p.G91Kfs*3), pathogenic

- The c.269_270dup (p.G91Kfs*3) variant in the SLC26A3 gene has been observed at a frequency of 0.0008% in the gnomAD v2.1.1 dataset.
- This variant has been observed in conjunction with another variant, or in a homozygous state, in individual(s) with congenital secretory chloride diarrhea 1 (PMID: 9718329, 30076350, 31680349, 33191723).
- This premature termination variant is predicted to cause nonsense-mediated decay (NMD) in a gene where loss-of-function is a known mechanism of disease.
- This variant has been described in ClinVar [ID: 55994].

Testing Methodology, Limitations, and Comments:

Next-generation sequencing (NGS)

Sequencing library prepared from genomic DNA isolated from a patient sample is enriched for targets of interest using standard hybridization capture protocols and PCR amplification (for targets specified below). NGS is then performed to achieve the standards of quality control metrics, including a minimum coverage of 99% of targeted regions at 20X sequencing depth. Sequencing data is aligned to human reference sequence, followed by deduplication, metric collection and variant calling (coding region +/- 20bp). Variants are then classified according to ACMGG/AMP standards of interpretation using publicly available databases including but not limited to ENSEMBL, HGMD Pro, ClinGen, ClinVar, 1000G, ESP and gnomAD. Variants predicted to be pathogenic or likely pathogenic for the specified diseases are reported. It should be noted that the data interpretation is based on our current understanding of the genes and variants at the time of reporting. Putative positive sequencing variants that do not meet internal quality standards or are within highly homologous regions are confirmed by Sanger sequencing or gene-specific long-range PCR as needed prior to reporting.

Copy Number Variant (CNV) analysis is limited to deletions involving two or more exons for all genes on the panel, in addition to specific known recurrent single-exon deletions. CNVs of small size may have reduced detection rate. This method does not detect gene inversions, single-exonic and sub-exonic deletions (unless otherwise specified), and duplications of all sizes (unless otherwise specified). Additionally, this method does not define the exact breakpoints of detected CNV events. Confirmation testing for copy number variation is performed by specific PCR, Multiplex Ligation-dependent Probe Amplification (MLPA), next generation sequencing, or other methodology.

This test may not detect certain variants due to local sequence characteristics, high/low genomic complexity, homologous sequence, or allele dropout (PCR-based assays). Variants within noncoding regions (promoter, 5'UTR, 3'UTR, deep intronic regions, unless otherwise specified), small deletions or insertions larger than 25bp, low-level mosaic variants, structural variants such as inversions, and/or balanced translocations may not be detected with this technology.

SPECIAL NOTES

For ABCC6, sequencing variants in exons 1-7 are not detected due to the presence of regions of high homology.

For CFTR, when the CFTR R117H variant is detected, reflex analysis of the polythymidine variations (5T, 7T and 9T) at the intron 9 branch/acceptor site of the CFTR gene will be performed. Multi-exon duplication analysis is included.

For CYP21A2, targets were enriched using long-range PCR amplification, followed by next generation sequencing. Duplication analysis will only be performed and reported when c.955C>T (p.Q319*) is detected. Sequencing and CNV analysis may have reduced sensitivity, if variants result from complex rearrangements, in trans with a gene deletion, or CYP21A2 gene duplication on one chromosome and deletion on the other chromosome. This analysis cannot detect sequencing variants located on the CYP21A2 duplicated copy.

For DDX11, sequencing variants in exons 7-11 and CNV for the entire gene are not analyzed due to high sequence homology.

For GJB2, CNV analysis of upstream deletions of GJB6-D13S1830 (309kb deletion) and GJB6-D13S1854 (232kb deletion) is included.

For HBA1/HBA2, CNV analysis is offered to detect common deletions of -alpha3.7, -alpha4.2, --MED, --SEA, --FIL, --THAI, --alpha20.5, and/or HS-40.

For OTOA, sequencing variants in exons 25-29 and CNV in exons 21-29 are not analyzed due to high sequence homology.

For RPGRIP1L, variants in exon 23 are not detected due to assay limitation.

For SAMD9, only p.K1495E variant will be analyzed and reported.

Friedreich Ataxia (FXN)

The GAA repeat region of the FXN gene is assessed by trinucleotide PCR assay and capillary electrophoresis. Variances of +/-1 repeat for normal alleles and up to +/-3 repeats for premutation alleles may occur. For fully penetrant expanded alleles, the precise repeat size cannot be determined, therefore the approximate allele size is reported. Sequencing and copy number variants are analyzed by next-generation sequencing analysis.

Friedreich Ataxia Repeat Categories

Categories	GAA Repeat Sizes
Normal	<34
Premutation	34 - 65
Full	>65

Spinal Muscular Atrophy (SMN1)

1 in 1061

The total combined copy number of SMN1 and SMN2 exon 7 is quantified based on NGS read depth. The ratio of SMN1 to SMN2 is calculated based on the read depth of a single nucleotide that distinguishes these two genes in exon 7. In addition to copy number analysis, testing for the presence or absence of a single

nucleotide polymorphism (g.27134T>G in intron 7 of SMN1) associated with the presence of a SMN1 duplication allele is performed using NGS. Ethnicity Two SMN1 copies carrier risk before g.27134T>G testing Carrier risk after g.27134T>G testing g.27134T>G ABSENT g.27134T>G PRESENT Caucasian 1 in 632 1 in 769 1 in 29 Ashkenazi Jewish 1 in 350 1 in 580 LIKELY CARRIER 1 in 628 1 in 702 LIKELY CARRIER African-American 1 in 121 1 in 396 1 in 34

Variant Classification

Hispanic

Only pathogenic or likely pathogenic variants are reported. Other variants including benign variants, likely benign variants, variants of uncertain significance, or inconclusive variants identified during this analysis may be reported in certain circumstances. Our laboratory's variant classification criteria are based on the ACMG and internal guidelines and our current understanding of the specific genes. This interpretation may change over time as more information about a gene and/or variant becomes available. Natera and its lab partner(s) may reclassify variants at certain intervals but may not release updated reports without a specific request made to Natera by the ordering provider. Natera may disclose incidental findings if deemed clinically pertinent to the test performed.

Negative Results

A negative carrier screening result reduces the risk for a patient to be a carrier of a specific disease but does not completely rule out carrier status. Please visit https://www.natera.com/panel-option/h-all/ for a table of carrier rates, detection rates, residual risks and promised variants/exons per gene. Carrier rates before and after testing vary by ethnicity and assume a negative family history for each disease screened and the absence of clinical symptoms in the patient. Any patient with a family history for a specific genetic disease will have a higher carrier risk prior to testing and, if the disease-causing mutation in their family is not included on the test, their carrier risk would remain unchanged. Genetic counseling is recommended for patients with a family history of genetic disease so that risk figures based on actual family history can be determined and discussed along with potential implications for reproduction. Horizon carrier screening has been developed to identify the reproductive risks for monogenic inherited conditions. Even when one or both members of a couple screen negative for pathogenic variants in a specific gene, the disease risk for their offspring is not zero. There is still a low risk for the condition in their offspring due to a number of different mechanisms that are not detected by Horizon including, but not limited to, pathogenic variant(s) in the tested gene or in a different gene not included on Horizon, pathogenic variant(s) in an upstream regulator, uniparental disomy, de novo mutation(s), or digenic or polygenic inheritance.

Additional Comments

These analyses generally provide highly accurate information regarding the patient's carrier status. Despite this high level of accuracy, it should be kept in mind that there are many potential sources of diagnostic error, including misidentification of samples, polymorphisms, or other rare genetic variants that interfere with analysis. Families should understand that rare diagnostic errors may occur for these reasons.
