

SPERM DONOR GENETIC TESTING SUMMARY Donor # 7527

Fairfax Cryobank recommends reviewing this genetic testing summary with your healthcare provider to determine suitability.

Last Updated: 06/30/2025

Donor Reported Ancestry: Russian Jewish Ancestry: No

Genetic Test*	Result	Comments
		Donor's Residual Risk**
Chromosome analysis (karyotype)	Normal male karyotype	No evidence of clinically significant chromosome abnormalities
Hemoglobin evaluation	Normal hemoglobin fractionation and MCV/MCH results	Reduced risk to be a carrier for sickle cell anemia, beta thalassemia, alpha thalassemia trait (aa/ and a-/a-) and other hemoglobinopathies
Expanded Genetic Disease Carrier Screening Panel attached - 549 diseases by gene sequencing and del/dup analysis.	Carrier: Biotinidase deficiency (BTD) Carrier: Medium-chain acyl-CoA dehydrogenase deficiency (ACADM) Carrier: Shwachman - Diamond Syndrome, SBDS - Related (SBDS-related) Negative for other genes tested.	Partner testing is recommended before using this donor.

^{*}No single test can screen for all genetic disorders. A negative screening result significantly reduces, but cannot eliminate, the risk for these conditions in a pregnancy.

^{**}Donor residual risk is the chance the donor is still a carrier after testing negative.

Patient Name: Donor 7527

CARRIER SCREENING REPORT

ABOUT THIS SCREEN: Horizon™ is a carrier screen for specific autosomal recessive and X-linked diseases. This information can help patients learn their risk of having a child with specific genetic conditions.

ORDER SELECTED: The Horizon Custom panel was ordered for this patient. Males are not

screened for X-linked diseases

FINAL RESULTS SUMMARY:

CARRIER for Biotinidase Deficiency

Positive for the pathogenic variant c.1330G>C (p.D444H) in the BTD gene. Please note that this BTD gene variant is a mild variant and is not expected to result in a disease phenotype when homozygous, unless present as part of a complex allele. If found in trans (on opposite chromosomes) with a severe pathogenic variant, the individual is expected to develop partial BIOTINIDASE DEFICIENCY. If this individual's partner is a carrier for BIOTINIDASE DEFICIENCY, their chance to have a child with this condition is 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

CARRIER for MEDIUM CHAIN ACYL-CoA DEHYDROGENASE DEFICIENCY

Positive for the pathogenic variant c.449_452del (p.T150Rfs*4) in the ACADM gene. If this individual's partner is a carrier for MEDIUM CHAIN ACYL-CoA DEHYDROGENASE DEFICIENCY, their chance to have a child with this condition is 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

CARRIER for Shwachman-Diamond Syndrome, SBDS-Related

Positive for the pathogenic variant c.258+2T>C in the SBDS gene. If this individual's partner is a carrier for SHWACHMAN-DIAMOND SYNDROME, SBDS-RELATED, their chance to have a child with this condition is 1 in 4 (25%). Carrier screening for this individual's partner is suggested.

Negative for 546 out of 549 diseases

No other pathogenic variants were detected in the genes that were screened. The patient's remaining carrier risk after the negative screening results is listed for each disease/gene on the Horizon website at https://www.natera.com/panel-option/h-all/. Please see the following pages of this report for a comprehensive list of all conditions included on this individual's screen.

Carrier screening is not diagnostic and may not detect all possible pathogenic variants in a given gene.

RECOMMENDATIONS

Individuals who would like to review their Horizon report with a Natera Laboratory Genetic Counselor may schedule a telephone genetic information session by calling 650-249-9090 or visiting naterasession.com. Clinicians with questions may contact Natera at 650-249-9090 or email support@natera.com. Individuals with positive results may wish to discuss these results with family members to allow them the option to be screened. Comprehensive genetic counseling to discuss the implications of these test results and possible associated reproductive risk is recommended.

BIOTINIDASE DEFICIENCY

Understanding Your Horizon Carrier Screen Results

What is Biotinidase Deficiency?

Biotinidase Deficiency is an inherited disorder in which the body is unable to reuse a B vitamin called biotin. This condition is treatable in affected infants and children by giving biotin. If this condition is not identified in infancy and treated, signs and symptoms typically appear in the first few months of life but can sometimes begin later in childhood. If untreated, Biotinidase Deficiency can cause delayed development, seizures, weak muscle tone (hypotonia), breathing problems, hearing and vision loss, problems with movement and balance, skin rashes, hair loss, and yeast infections. Some children have a milder form of this condition, and some never develop symptoms. Lifelong treatment with oral biotin supplements can prevent these complications from occurring. With early diagnosis and treatment with biotin, people with Biotinidase Deficiency can live healthy lives with no symptoms. Clinical trials involving potential new treatments for this condition may be available (see www.clinicaltrials.gov).

What causes Biotinidase Deficiency?

Biotinidase Deficiency is caused by a gene change, or mutation, in both copies of the BTD gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of the BTD gene do not work correctly, it leads to the symptoms described above Biotinidase Deficiency is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the BTD gene to have a child with the condition. People who are carriers for Biotinidase Deficiency are usually healthy and do not have symptoms nor do they have Biotinidase Deficiency themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for Biotinidase Deficiency, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their BTD gene mutations to the child, who will then have the condition. Individuals found to carry more than one mutation for Biotinidase Deficiency should discuss their risk for having an affected child, and any potential effects to their own health, with their health care provider.

What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for Biotinidase Deficiency ordered by a health care professional. If your partner is not found to be a carrier for Biotinidase Deficiency your risk of having a child with the condition is greatly reduced. Couples at risk of having a baby with Biotinidase Deficiency can opt to have prenatal diagnosis done through chorionic villus sampling (CVS) or amniocentesis during pregnancy to test the fetus for that condition. Babies at risk for Biotinidase Deficiency should be tested after birth for this condition. Although Biotinidase Deficiency is routinely screened for as part of the Newborn Screening program in all US states, babies at 25% for this condition may need diagnostic testing in addition to newborn screening. If you are not yet pregnant, your partner can have carrier screening for Biotinidase Deficiency ordered by a health care professional. If your partner is found to be a carrier for Biotinidase Deficiency, the following options are available:

- Natural pregnancy with or without prenatal diagnostic testing of the fetus or testing the baby after birth for Biotinidase Deficiency
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for Biotinidase Deficiency
- Adoption or use of a sperm or egg donor who is not a carrier for Biotinidase Deficiency Please note that although options such as prenatal diagnosis, PGD, and use of sperm or egg donors are available, they may not be routinely selected for Biotinidase Deficiency as it is considered a highly treatable condition.

MEDIUM CHAIN ACYL-Coa DEHYDROGENASE DEFICIENCY

Understanding Your Horizon Carrier Screen Results

What is Medium Chain Acyl-CoA Dehydrogenase Deficiency?

Medium Chain Acyl-CoA Dehydrogenase (MCAD) Deficiency is an inherited disorder that causes the body to be unable to break down certain types of fat. It is a type of inherited condition called a fatty acid oxidation disorder. Children born with MCAD Deficiency are typically unable to change some of the fats from food that they eat into energy that the body needs to work properly. As a result, blood sugar can drop (hypoglycemia) and fatty acids build up in the body. If left untreated, MCAD Deficiency can lead to health problems such as fatigue, vomiting, seizures, breathing problems, liver problems, brain damage, coma, and even death. With early diagnosis and treatment – which typically includes a special medical diet, specific supplements, and avoiding going without food for long periods – people with MCAD Deficiency can often lead healthy lives. Some people with MCAD Deficiency have mild symptoms that may not start until later in childhood or even adulthood and some may never show symptoms. Clinical trials involving potential new treatments for this condition may be available (see www.clinicaltrials.gov).

What causes Medium Chain Acyl-CoA Dehydrogenase Deficiency?

MCAD Deficiency is caused by a gene change, or mutation in both copies of the ACADM gene pair. These mutations cause the genes to not work properly or not work at all. The job of the ACADM genes is to make an enzyme called medium-chain acyl-CoA dehydrogenase, which is needed to break down a type of fat called medium-chain fatty acids found in food and the body's fat. When both copies of this gene do not work correctly, it can lead to the symptoms described above. MCAD Deficiency is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the ACADM gene to have a child with MCAD Deficiency. People who are carriers for MCAD Deficiency are usually healthy and do not have symptoms nor do they have MCAD Deficiency themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for MCAD Deficiency, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their ACADM gene mutations to the child, who will then have MCAD Deficiency. Individuals found to carry more than one mutation for MCAD Deficiency should discuss any potential risks to their own health and their risk for having an affected child with their health care provider.

What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for MCAD Deficiency ordered by a health care professional. If your partner is not found to be a carrier for MCAD Deficiency, your risk of having a child with MCAD Deficiency is greatly reduced. Couples at risk of having a baby with MCAD Deficiency can opt to have prenatal diagnosis done through chorionic villus sampling (CVS) or amniocentesis during pregnancy or can choose to have the baby tested after birth for this condition. Although MCAD Deficiency is screened for as part of the newborn screening program in all states, babies at 25% risk for this condition may need diagnostic testing in addition to newborn screening. If you are not yet pregnant, your partner can have carrier screening for MCAD Deficiency ordered by a health care professional. If your partner is found to be a carrier for MCAD Deficiency, you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnosis of the fetus or testing the baby after birth for MCAD Deficiency
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for MCAD Deficiency
- Adoption or use of a sperm or egg donor who is not a carrier for MCAD Deficiency

SHWACHMAN-DIAMOND SYNDROME, SBDS-RELATED

Understanding Your Horizon Carrier Screen Results

What is Shwachman-Diamond Syndrome, SBDS-Related?

Shwachman-Diamond Syndrome, SBDS-Related is an inherited disorder that affects the bones, the bone marrow, and the pancreas. Bone abnormalities are commonly seen in the hips and knees and sometimes include short ribs and narrow rib cage, which can lead to serious breathing problems. Affected individuals have slow bone growth and short stature. The bone marrow problems in Shwachman-Diamond Syndrome, SBDS-Related include lower production of white blood cells that fight infections (called neutropenia), causing an increased numbers of infections. Some affected individuals also have a reduced number of red blood cells, which leads to anemia and less oxygen getting to the cells of the body; and some have a reduced number of platelets, which leads to easy bruising and prolonged bleeding. The bone marrow problems also increase the risk for a type of cancer called Acute Myeloid Leukemia (AML). Individuals with Shwachman-Diamond Syndrome, SBDS-Related do not make enough digestive enzymes in their pancreas (called pancreatic insufficiency) and have trouble digesting their food. If not treated, this causes slow growth, lack of weight gain, and malnutrition. Symptoms sometimes also include problems with the heart, eyes, teeth, skin, and endocrine system. Some affected children have delayed development and speech. Currently there is no cure for this disorder and treatment includes daily supplementation with pancreatic enzymes and doctor-prescribed vitamins along with other medical management based on symptoms. In some cases, affected individuals have been treated with stem cell transplantation from cord blood or bone marrow. Couples at risk of having an affected child may consider cord blood banking, as siblings have a higher chance of being a match for stem cell transplantation than a non-related individual. More information can be found at: https://parentsguidecordblood.org/en. Clinical trials involving potential new treatments for this condition may be available (see <a h

What causes Shwachman-Diamond Syndrome, SBDS-Related?

Shwachman-Diamond Syndrome, SBDS-Related is caused by changes, or mutations, in both copies of the SBDS gene pair. These mutations cause the genes to not work properly or not work at all. When both copies of the SBDS gene do not work correctly it leads to the symptoms described above. Shwachman-Diamond Syndrome, SBDS-Related is inherited in an autosomal recessive manner. This means that, in most cases, both parents must be carriers of a mutation in one copy of the SBDS gene to have a child with Shwachman-Diamond Syndrome, SBDS-Related. People who are carriers for Shwachman-Diamond Syndrome, SBDS-Related are usually healthy and do not have symptoms, nor do they have Shwachman-Diamond Syndrome, SBDS-Related themselves. Usually a child inherits two copies of each gene, one copy from the mother and one copy from the father. If the mother and father are both carriers for Shwachman-Diamond Syndrome, SBDS-Related, there is a 1 in 4, or 25%, chance in each pregnancy for both partners to pass on their SBDS gene mutations to the child, who will then have this disorder. Individuals found to carry more than one mutation for Shwachman-Diamond Syndrome, SBDS-Related should discuss their risk for having an affected child, and any specific risks to their own health, with their health care provider. There are a number of other forms of Shwachman-Diamond Syndrome, SBDS-Related, each caused by mutations in different genes. A person who is a carrier of a mutation in the SBDS gene is not likely to be at increased risk for having a child with these other forms.

What can I do next?

You may wish to speak with a local genetic counselor about your carrier test results. A genetic counselor in your area can be located on the National Society of Genetic Counselors website (www.nsgc.org). Your siblings and other relatives are at increased risk to also have this mutation. You are encouraged to inform your family members of your test results as they may wish to consider being tested themselves. If you are pregnant, your partner can have carrier screening for Shwachman-Diamond Syndrome, SBDS-Related ordered by a health care professional. If your partner is not found to be a carrier for Shwachman-Diamond Syndrome, SBDS-Related, your risk of having an affected child is greatly reduced. If your partner is found to be a carrier, you can consider having prenatal diagnostic testing done through chorionic villus sampling (CVS) or amniocentesis during pregnancy to test the fetus, or you can have the baby tested after birth for this disorder. If you are not yet pregnant, your partner can have carrier screening for Shwachman-Diamond Syndrome, SBDS-Related ordered by a health care professional. If your partner is found to be a carrier for Shwachman-Diamond Syndrome, SBDS-Related, you have several reproductive options to consider:

- Natural pregnancy with or without prenatal diagnostic testing of the fetus or testing the baby after birth for Shwachman-Diamond Syndrome, SBDS-Related
- Preimplantation genetic diagnosis (PGD) with in vitro fertilization (IVF) to test embryos for Shwachman-Diamond Syndrome, SBDS-Related
- Adoption or use of a sperm or egg donor who is not a carrier for Shwachman-Diamond Syndrome, SBDS-Related

VARIANT DETAILS

ACADM, c.449_452del (p.T150Rfs*4), heterozygous, pathogenic

- The c.449 452del (p.T150Rfs*4) variant in the ACADM gene has been observed at a frequency of 0.0020% in the gnomAD v2.1.1 dataset.
- This variant has been reported in a homozygous state or in conjunction with another variant in individual(s) with medium chain acyl-CoA dehydrogenase deficiency (PMID: 15915086).
- This premature termination variant is predicted to cause nonsense-mediated decay (NMD) in a gene where loss-of-function is a known mechanism of disease.
- This variant has been reported in ClinVar [ID: 189036].

BTD, c.1330G>C (p.D444H), heterozygous, pathogenic

- The c.1330G>C (p.D444H) variant in the BTD gene has been observed at a frequency of 3.1839% in the gnomAD v2.1.1 dataset.
- This variant has been reported in a homozygous state or in conjunction with another variant in individual(s) with partial biotinidase deficiency. This variant is a mild variant and is not expected to result in a disease phenotype when homozygous, unless present as part of a complex allele. If found in trans (on opposite chromosomes) with a severe pathogenic variant, the individual is expected to develop partial biotinidase deficiency.
- This variant has been reported in ClinVar [ID: 1900].

SBDS, c.258+2T>C, heterozygous, pathogenic

- The c.258+2T>C variant in the SBDS gene has been observed at a frequency of 0.3879% in the gnomAD v2.1.1 dataset.
- This variant has been reported in a homozygous state or in conjunction with another variant in individual(s) with Shwachman-Diamond syndrome (PMID: 12496757, 14749921, 15860664, 22935661).
- This canonical splicing variant is predicted to alter the reading frame and cause nonsense-mediated decay (NMD) in a gene where loss-of-function is a known mechanism of disease.
- This variant has been reported in ClinVar [ID: 3196].

Testing Methodology, Limitations, and Comments:

Next-generation sequencing (NGS)

Sequencing library prepared from genomic DNA isolated from a patient sample is enriched for targets of interest using standard hybridization capture protocols and PCR amplification (for targets specified below). NGS is then performed to achieve the standards of quality control metrics, including a minimum coverage of 99% of targeted regions at 20X sequencing depth. Sequencing data is aligned to human reference sequence, followed by deduplication, metric collection and variant calling (coding region +/- 20bp). Variants are then classified according to ACMGG/AMP standards of interpretation using publicly available databases including but not limited to ENSEMBL, HGMD Pro, ClinGen, ClinVar, 1000G, ESP and gnomAD. Variants predicted to be pathogenic or likely pathogenic for the specified diseases are reported. It should be noted that the data interpretation is based on our current understanding of the genes and variants at the time of reporting. Putative positive sequencing variants that do not meet internal quality standards or are within highly homologous regions are confirmed by Sanger sequencing or gene-specific long-range PCR as needed prior to reporting.

Copy Number Variant (CNV) analysis is limited to deletions involving two or more exons for all genes on the panel, in addition to specific known recurrent single-exon deletions. CNVs of small size may have reduced detection rate. This method does not detect gene inversions, single-exonic and sub-exonic deletions (unless otherwise specified), and duplications of all sizes (unless otherwise specified). Additionally, this method does not define the exact breakpoints of detected CNV events. Confirmation testing for copy number variation is performed by specific PCR, Multiplex Ligation-dependent Probe Amplification (MLPA), next generation sequencing, or other methodology.

This test may not detect certain variants due to local sequence characteristics, high/low genomic complexity, homologous sequence, or allele dropout (PCR-based assays). Variants within noncoding regions (promoter, 5'UTR, 3'UTR, deep intronic regions, unless otherwise specified), small deletions or insertions larger than 25bp, low-level mosaic variants, structural variants such as inversions, and/or balanced translocations may not be detected with this technology.

SPECIAL NOTES

For ABCC6, variants in exons 1-9 are not detected due to the presence of regions of high homology.

For CFTR, when the CFTR R117H variant is detected, reflex analysis of the polythymidine variations (5T, 7T and 9T) at the intron 9 branch/acceptor site of the CFTR gene will be performed.

For CYP21A2, targets were enriched using long-range PCR amplification, followed by next generation sequencing. Duplication analysis will only be performed and reported when c.955C>T (p.Q319*) is detected. Sequencing and CNV analysis may have reduced sensitivity, if variants result from complex rearrangements, in trans with a gene deletion, or CYP21A2 gene duplication on one chromosome and deletion on the other chromosome. This analysis cannot detect sequencing variants located on the CYP21A2 duplicated copy.

For DDX11, only NM_030653.3:c.1763 - 1G > C variant will be analyzed and reported.

For HBA1/HBA2, CNV analysis is offered to detect common deletions of -alpha3.7, -alpha4.2, --MED, --SEA, --FIL, --THAI, --alpha20.5, and/or HS-40.

For OTOA, variants in exons 20 - 28 are not analyzed due to high sequence homology.

For RPGRIP1L, variants in exon 23 are not detected due to assay limitation.

For SAMD9, only p.K1495E variant will be analyzed and reported.

Friedreich Ataxia (FXN)

The GAA repeat region of the FXN gene is assessed by trinucleotide PCR assay and capillary electrophoresis. Variances of +/-1 repeat for normal alleles and up to +/-3 repeats for premutation alleles may occur. For fully penetrant expanded alleles, the precise repeat size cannot be determined, therefore the approximate allele size is reported. Sequencing and copy number variants are analyzed by next-generation sequencing analysis.

Friedreich Ataxia Repeat Categories

Categories	GAA Repeat Sizes
Normal	<34
Premutation	34 - 65
Full	>65

Spinal Muscular Atrophy (SMN1)

The total combined copy number of SMN1 and SMN2 exon 7 is quantified based on NGS read depth. The ratio of SMN1 to SMN2 is calculated based on the read depth of a single nucleotide that distinguishes these two genes in exon 7. In addition to copy number analysis, testing for the presence or absence of a single nucleotide polymorphism (g.27134T>G in intron 7 of SMN1) associated with the presence of a SMN1 duplication allele is performed using NGS.

Report Date:

Ethnicity	Two SMN1 copies carrier risk before g.27134T>G testing	Carrier risk after g.27134T	Carrier risk after g.27134T>G testing	
		g.27134T>G ABSENT	g.27134T>G PRESENT

African-American	1 in 121	1 in 396	1 in 34	
Hispanic	1 in 1061	1 in 1762	1 in 140	

Variant Classification

Only pathogenic or likely pathogenic variants are reported. Other variants including benign variants, likely benign variants, variants of uncertain significance, or inconclusive variants identified during this analysis may be reported in certain circumstances. Our laboratory's variant classification criteria are based on the ACMG and internal guidelines and our current understanding of the specific genes. This interpretation may change over time as more information about a gene and/or variant becomes available. Natera and its lab partner(s) may reclassify variants at certain intervals but may not release updated reports without a specific request made to Natera by the ordering provider. Natera may disclose incidental findings if deemed clinically pertinent to the test performed.

Negative Results

A negative carrier screening result reduces the risk for a patient to be a carrier of a specific disease but does not completely rule out carrier status. Please visit https://www.natera.com/panel-option/h-all/ for a table of carrier rates, detection rates, residual risks and promised variants/exons per gene. Carrier rates before and after testing vary by ethnicity and assume a negative family history for each disease screened and the absence of clinical symptoms in the patient. Any patient with a family history for a specific genetic disease will have a higher carrier risk prior to testing and, if the disease-causing mutation in their family is not included on the test, their carrier risk would remain unchanged. Genetic counseling is recommended for patients with a family history of genetic disease so that risk figures based on actual family history can be determined and discussed along with potential implications for reproduction. Horizon carrier screening has been developed to identify the reproductive risks for monogenic inherited conditions. Even when one or both members of a couple screen negative for pathogenic variants in a specific gene, the disease risk for their offspring is not zero. There is still a low risk for the condition in their offspring due to a number of different mechanisms that are not detected by Horizon including, but not limited to, pathogenic variant(s) in the tested gene or in a different gene not included on Horizon, pathogenic variant(s) in an upstream regulator, uniparental disomy, de novo mutation(s), or digenic or polygenic inheritance.

Additional Comments

These analyses generally provide highly accurate information regarding the patient's carrier status. Despite this high level of accuracy, it should be kept in mind that there are many potential sources of diagnostic error, including misidentification of samples, polymorphisms, or other rare genetic variants that interfere with analysis. Families should understand that rare diagnostic errors may occur for these reasons.
